Welcome to GNSS-SDR!

GNSS-SDR is an open-source GNSS software receiver freely available to the research community. This project provides a common framework for GNSS signal processing which can operate in a variety of computer platforms. This tool is intended to foster collaboration, increase awareness, and reduce development costs in the field of GNSS receiver design and customized use of GNSS signals.

For details about GNSS-SDR and using it, please see the **main project page** or browse **the source code at GitHub**. You could be also interested in **subscribing to the mailing list**.

1.2 Overview

GNSS-SDR provides an interface to different suitable RF front-ends and implements all the receiver chain up to the navigation solution. Its design allows any kind of customization, including interchangeability of signal sources, signal processing algorithms, interoperability with other systems, output formats, and offers interfaces to all the intermediate signals, parameters and variables. The goal is to write efficient and truly reusable code, easy to read and maintain, with fewer bugs, and producing highly optimized executables in a variety of hardware platforms and operating systems. In that sense, the challenge consists of defining a gentle balance within level of abstraction and performance. GNSS-SDR runs in a personal computer and provides interfaces through USB and Ethernet buses to a variety of either commercially available or custom-made RF front-ends, adapting the processing algorithms to different sampling frequencies, intermediate frequencies and sample resolutions. This makes possible rapid prototyping of specific receivers intended, for instance, to geodetic applications, observation of the ionospheric impact on navigation signals, GNSS reflectometry, signal quality monitoring, or carrier-phase based navigation techniques.

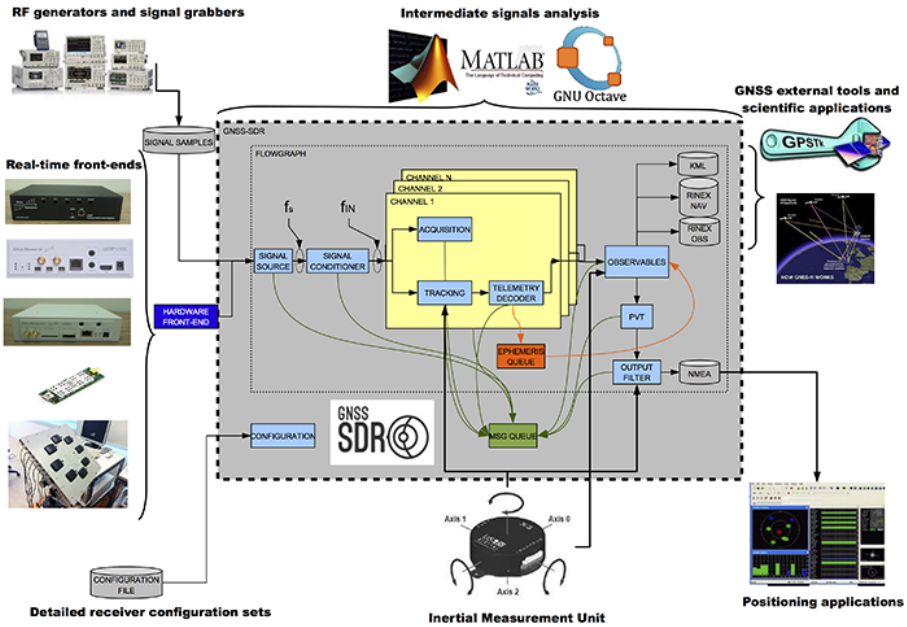

Figure 1.2 Overview

As signal inputs, it accepts:

- Raw data file captured with a data grabber (digitized at some intermediate frequency or directly at baseband).
- Any suitable RF configuration that can be driven by the Universal Software Radio Peripheral Hardware Driver (UHD). This includes all current and future Ettus Research products. The USRP1 + DBSRX 2.2 daughterboard is an example of working configuration for GPS L1 C/A and Galileo E1B and E1C signals.

- Experimentally, with some USB DVB-T dongles based on the Realtek RTL2832U chipset.
- For mathematical representations of the targeted signals, check out the Signal model page.

As outputs, it provides:

- Dump of intermediate signals (configurable by the user)
- The processing is logged at a system temporary folder (usually, /tmp)
- Observables in form of RINEX file (experimental)
- Navigation message data in form of RINEX file
- Position, Velocity and Time solution in KML format and NMEA

1.3 Building GNSS-SDR

In principle, GNSS-SDR can be built in any Unix-like system. In practice, it depends on being able to install all the required dependencies. See the building guide page for details about the project's dependencies and build process. Mainly, it consists on installing GNU Radio plus some few more libraries:

- Armadillo, a C++ linear algebra library,
- Boost, a set of free peer-reviewed portable C++ source libraries,
- Gflags, a library that implements commandline flags processing,
- Glog, a library that implements application-level logging,
- Googletest, Google's framework for writing C++ tests,
- Mako, a template library written in Python,
- Matio, a MATLAB MAT File I/O Library,
- Protocol Buffers, a language-neutral, platform-neutral extensible mechanism for serializing structured data,
- PugiXML, a light-weight, simple and fast XML parser for C++ with XPath support,
- Volk, a Vector-Optimized Library of Kernels which provides an abstraction of optimized math routines targeting several SIMD processors,

and, optionally,

- GNU Radio modules for hardware interface (gr-uhd, gr-osmosdr, gr-iio),
- Benchmark, a library to benchmark code snippets,
- Gperftools, which provides fast, multi-threaded malloc() and performance analysis tools.

After all dependencies are installed, clone the GNSS-SDR repository:

```
$ git clone https://github.com/gnss-sdr/gnss-sdr
```

This will create a folder named gnss-sdr with the following structure:

```
|-gnss-sdr
|---cmake       <- CMake-related files
|---conf        <- Configuration files. Each file represents one receiver.
|---docs        <- Contains documentation-related files
|---install     <- Executables
|---src         <- Source code folder
|-----algorithms
|-------PVT
|-------acquisition
|-------channel
|-------conditioner
|-------data_type_adapter
|-------input_filter
|-------libs
|-------observables
|-------resampler
|-------signal_source
|-------telemetry_decoder
|-------tracking
|-----core
|-------interfaces
|-------libs
|-------receiver
|-------system_parameters
|-----main
|---tests
|---utils     <- some utilities (e.g. Matlab scripts)
```

You are now ready to build GNSS-SDR by using CMake as building tool:

```
$ cd gnss-sdr && mkdir build && cd build
$ cmake ..
$ make
```

If everything goes well, three new executables will be created at `gnss-sdr/install`, namely `gnss-sdr`, `volk_gnsssdr_profile` and `run_tests`. You can run them from that folder, but if you prefer to install gnss-sdr on your system and have it available anywhere else, do:

```
$ sudo make install
```

This will make a copy of the conf/ folder into /usr/local/share/gnss-sdr/conf for your reference. We suggest to create a working directory at your preferred location and store your own configuration and data files there.

You can create the documentation by doing:

```
$ make doc
```

from the building folder. In both cases, Doxygen will generate HTML documentation that can be retrieved pointing your browser of preference to `gnss-sdr/docs/html/index.html`.

There are two more extra targets available. In the building folder:

```
$ make doc-clean
```

will remove the content of previously-generated documentation and, if a LaTeX installation is detected in your system,

```
$ make pdfmanual
```

will create a PDF manual at `gnss-sdr/docs/GNSS-SDR_manual.pdf`. Please note that the PDF generation requires some fonts to be installed on the host system. In Ubuntu, those fonts do not come by default. You can install them by doing:

```
$ sudo apt install texlive-fonts-recommended
```

and then run `cmake ../` and `make pdfmanual` again.

1.3.1 Debug and Release builds

By default, CMake will build the Release version, meaning that the compiler will generate a faster, optimized executable. This is the recommended build type when using a RF front-end and you need to attain real time. If working with a file (and thus without real-time constraints), you may want to obtain more information about the internals of the receiver, as well as more fine-grained logging. This can be done by building the Debug version, by doing:

```
$ cd gnss-sdr && mkdir build-debug && cd build-debug
$ cmake -DCMAKE_BUILD_TYPE=Debug ..
$ make
```

1.3.2 Updating GNSS-SDR

If you checked out GNSS-SDR some days ago, it is possible that some developer had updated files at the Git repository. You can update your local copy by doing:

```
$ git checkout next
$ git pull https://github.com/gnss-sdr/gnss-sdr next
```

Before rebuilding the source code, it is safe (and recommended) to remove the remainders of old builds:

```
$ cd <building folder>
$ sudo make uninstall  ; if you installed it before
$ rm -rf *
```

You can also check The Git Book for more information about Git usage.

1.4 Using GNSS-SDR

With GNSS-SDR, you can define you own receiver, work with captured raw data or from a RF front-end, dump into files intermediate signals, or tune every single algorithm used in the Signal Processing plane. All the configuration is done in a single file. Those configuration files reside at the `gnss-sdr/conf` folder. By default, the executable `gnss-sdr` will read the configuration available at `gnss-sdr/conf/gnss-sdr.conf`. You can edit that file to fit your needs, or even better, define a new `my_receiver.conf` file with your own configuration. This new receiver can be done by invoking gnss-sdr with the `-config_file` flag pointing to your configuration file:

```
$ gnss-sdr --config_file=../conf/my_receiver.conf
```

You can see a guide of available implementations at the online documentation. That folder contains other working examples as well. If you have a working configuration and want to share it will others, please email it to the **GNSS-SDR developers mailing list** and we will be happy to upload it to the server.

You can use a single configuration file for processing different data files, specifying the file to be processed with the `-signal_source` flag:

```
$ gnss-sdr --config_file=../conf/my_receiver.conf --signal_source=./my_captured_data.dat
```

This will override the `SignalSource.filename` specified in the configuration file.

You can get a complete list of available commandline flags by doing:

```
$ gnss-sdr --help
```

1.5 Control plane

GNSS-SDR's main method initializes the logging library, processes the command line flags, if any, provided by the user and instantiates a ControlThread object. Its constructor reads the configuration file, creates a control queue and creates a flowgraph according to the configuration. Then, the program's main method calls the run() method of the instantiated object, an action that connects the flowgraph and starts running it. After that, and until a stop message is received, it reads control messages sent by the receiver's modules through a safe-thread queue and processes them. Finally, when a stop message is received, the main method executes the destructor of the ControlThread object, which deallocates memory, does other cleanup and exits the program.

The GNSSFlowgraph class is responsible for preparing the graph of blocks according to the configuration, running it, modifying it during run-time and stopping it. Blocks are identified by its role. This class knows which roles it has to instantiate and how to connect them. It relies on the configuration to get the correct instances of the roles it needs and then it applies the connections between GNU Radio blocks to make the graph ready to be started. The complexity related to managing the blocks and the data stream is handled by GNU Radio's `gr::top_block` class. GNSSFlowgraph wraps the `gr::top_block` instance so we can take advantage of the GNSS block factory, the configuration system and the processing blocks. This class is also responsible for applying changes to the configuration of the flowgraph during run-time, dynamically reconfiguring channels: it selects the strategy for selecting satellites. This can range from a sequential search over all the satellites' ID to smarter approaches that determine what are the satellites most likely in-view based on rough estimations of the receiver position in order to avoid searching satellites in the other side of the Earth.

The Control Plane is in charge of creating a flowgraph according to the configuration and then managing the modules. Configuration allows users to define in an easy way their own custom receiver by specifying the flowgraph (type of signal source, number of channels, algorithms to be used for each channel and each module, strategies for satellite selection, type of output format, etc.). Since it is difficult to foresee what future module implementations will be needed in terms of configuration, we used a very simple approach that can be extended without a major impact in the code. This can be achieved by simply mapping the names of the variables in the modules with the names of the parameters in the configuration.

1.5.1 Configuration

Properties are passed around within the program using the ConfigurationInterface class. There are two implementations of this interface: FileConfiguration and InMemoryConfiguration. FileConfiguration reads the properties (pairs of property name and value) from a file and stores them internally. InMemoryConfiguration does not read from a file; it remains empty after instantiation and property values and names are set using the set property method. FileConfiguration is intended to be used in the actual GNSS-SDR application whereas InMemoryConfiguration is intended to be used in tests to avoid file-dependency in the file system. Classes that need to read configuration parameters will receive instances of ConfigurationInterface from where they will fetch the values. For instance, parameters related to SignalSource should look like this:

```
SignalSource.parameter1=value1
SignalSource.parameter2=value2
```

The name of these parameters can be anything but one reserved word: implementation. This parameter indicates in its value the name of the class that has to be instantiated by the factory for that role. For instance, if our signal source is providing data already at baseband and thus we want to use the implementation Pass_Through for module SignalConditioner, the corresponding line in the configuration file would be

```
SignalConditioner.implementation=Pass_Through
```

Since the configuration is just a set of property names and values without any meaning or syntax, the system is very versatile and easily extendable. Adding new properties to the system only implies modifications in the classes that will make use of these properties. In addition, the configuration files are not checked against any strict syntax so it is always in a correct status (as long as it contains pairs of property names and values in `INI format`).

1.5.2 GNSS block factory

Hence, the application defines a simple accessor class to fetch the configuration pairs of values and passes them to a factory class called GNSSBlockFactory. This factory decides, according to the configuration, which class needs to be instantiated and which parameters should be passed to the constructor. Hence, the factory encapsulates the complexity of blocks' instantiation. With that approach, adding a new block that requires new parameters will be as simple as adding the block class and modifying the factory to be able to instantiate it. This loose coupling between the blocks' implementations and the syntax of the configuration enables extending the application capacities in a high degree. It also allows to produce fully customized receivers, for instance a testbed for acquisition algorithms, and to place observers at any point of the receiver chain.

1.6 Signal Processing plane

GNU Radio's class `gr::basic_block` is the abstract base class for all signal processing blocks, a bare abstraction of an entity that has a name and a set of inputs and outputs. It is never instantiated directly; rather, this is the abstract parent class of both `gr::hier_block2`, which is a recursive container that adds or removes processing or hierarchical blocks to the internal graph, and `gr::block`, which is the abstract base class for all the processing blocks.

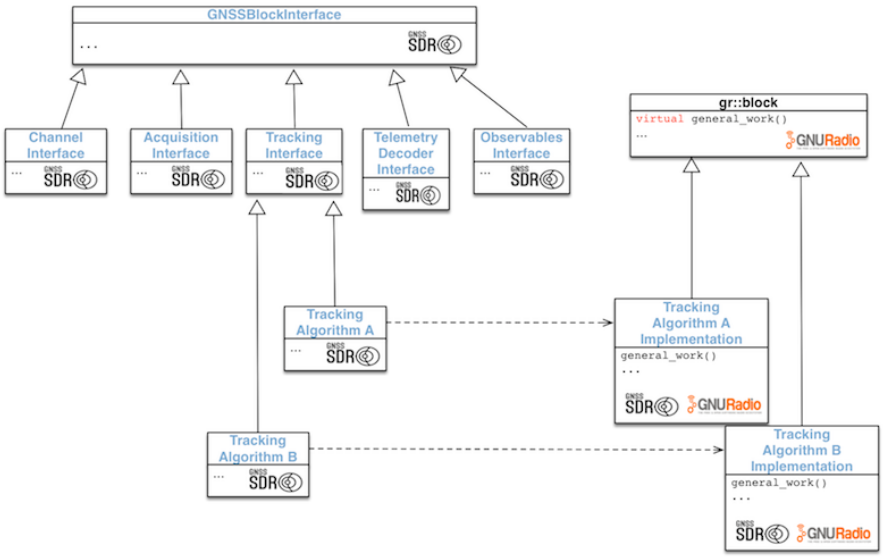

Figure 1.3 Class hierarchy of signal processing blocks

A signal processing flow is constructed by creating a tree of hierarchical blocks, which at any level may also contain terminal nodes that actually implement signal processing functions.

Class `gr::top_block` is the top-level hierarchical block representing a flowgraph. It defines GNU Radio runtime functions used during the execution of the program: run(), start(), stop(), wait(), etc. A a subclass called GNSSBlockInterface is the common interface for all the GNSS-SDR modules. It defines pure virtual methods, that are required to be implemented by a derived class.

Subclassing GNSSBlockInterface, we defined interfaces for the GNSS receiver blocks depicted in the figure above. This hierarchy provides the definition of different algorithms and different implementations, which will be instantiated according to the configuration. This strategy allows multiple implementations sharing a common interface, achieving the objective of decoupling interfaces from implementations: it defines a family of algorithms, encapsulates each one, and makes them interchangeable. Hence, we let the algorithm vary independently from the program that uses it.

1.6.1 Signal Source

The input of a software receiver are the raw bits that come out from the front-end's analog-to-digital converter (ADC). Those bits can be read from a file stored in the hard disk or directly in real-time from a hardware device through USB or Ethernet buses.

The Signal Source module is in charge of implementing the hardware driver, that is, the portion of the code that communicates with the RF front-end and receives the samples coming from the ADC. This communication is usually performed through USB or Ethernet buses. Since real-time processing requires a highly optimized implementation of the whole receiver, this module also allows to read samples from a file stored in a hard disk, and thus processing without time constraints. Relevant parameters of those samples are the intermediate frequency (or baseband I&Q components), the sampling rate and number of bits per sample, that must be specified by the user in the configuration file.

This module also performs bit-depth adaptation, since most of the existing RF front-ends provide samples quantized with 2 or 3 bits, while operations inside the processor are performed on 32- or 64-bit words, depending on its architecture. Although there are implementations of the most intensive computational processes (mainly correlation) that take advantage of specific data types and architectures for the sake of efficiency, the approach is processor-specific and hardly portable. We suggest to keep signal samples in standard data types and letting the compiler select the best library version (implemented using SIMD or any other processor-specific technology) of the required routines for a given processor.

Example: FileSignalSource

The user can configure the receiver for reading from a file, setting in the configuration file the data file location, sample format, and the sampling frequency and intermediate frequency at what the signal was originally captured.

```
;######### SIGNAL_SOURCE CONFIG ############
SignalSource.implementation=File_Signal_Source

The user may prefer to use a UHD-compatible RF front-end and try real-time processing. For instance, for a USRP1 + DBSRX daughterboard, use:

SignalSource.subdevice=B:0 ; UHD subdevice specification (for USRP1 use A:0 or B:0)
```

Other examples are available at `gnss-sdr/conf`.

1.6.2 Signal Conditioner

The signal conditioner is in charge of resampling the signal and delivering a reference sample rate to the downstream processing blocks, acting as a facade between the signal source and the synchronization channels, providing a simplified interface to the input signal. In case of multiband front-ends, this module would be in charge of providing a separated data stream for each band.

1.6.3 Channel

A channel encapsulates all signal processing devoted to a single satellite. Thus, it is a large composite object which encapsulates the Acquisition, Tracking and Decoding of the navigation message modules. As a composite object, it can be treated as a single entity, meaning that it can be easily replicated. Since the number of channels is selectable by the user in the configuration file, this approach helps improving the scalability and maintainability of the receiver.

This module is also in charge of managing the interplay between acquisition and tracking. Acquisition can be initialized in several ways, depending on the prior information available (called cold start when the receiver has no information about its position nor the satellites almanac; warm start when a rough location and the approximate time of day are available, and the receiver has a recently recorded almanac broadcast; or hot start when the receiver was tracking a satellite and the signal line of sight broke for a short period of time, but the ephemeris and almanac data is still valid, or this information is provided by other means), and an acquisition process can finish deciding that the satellite is not present, that longer integration is needed in order to confirm the presence of the satellite, or declaring the satellite present. In the latter case, acquisition process should stop and trigger the tracking module with coarse estimations of the synchronization parameters.

The abstract class ChannelInterface represents an interface to a channel GNSS block. Check Channel for an actual implementation.

1.6.3.1 Acquisition

The first task of a GNSS receiver is to detect the presence or absence of in-view satellites. This is done by the acquisition system process, which also provides a coarse estimation of two signal parameters: the frequency shift with respect to the nominal IF frequency, and a delay term which allows the receiver to create a local code aligned with the incoming code. AcquisitionInterface is the common interface for all the acquisition algorithms and their corresponding implementations. Algorithms' interface, that may vary depending on the use of information external to the receiver, such as in Assisted GNSS, is defined in classes referred to as *adapters*. These adapters wrap the GNU Radio blocks interface into a compatible interface expected by AcquisitionInterface. This allows the use of existing GNU Radio blocks derived from `gr::block`, and ensures that newly developed implementations will also be reusable in other GNU Radio-based applications. Moreover, it adds still another layer of abstraction, since each given acquisition algorithm can have different implementations (for instance using different numerical libraries). In such a way, implementations can be continuously improved without having any impact neither on the algorithm interface nor the general acquisition interface.

Check PcpsAcquisitionAdapter for an example of an adapter from a Parallel Code Phase Search (PCPS) acquisition block to AcquisitionInterface, and pcps_acquisition for an example of a block implementation. The source code of all the available acquisition algorithms is located at:

```
|-gnss-sdr
|---src
|-----algorithms
|-------acquisition
|---------adapters          <- Adapters of the processing blocks to an AcquisitionInterface
|---------gnuradio_blocks   <- Signal processing blocks implementation
```

The user can select a given implementation for the algorithm to be used in each receiver channel, as well as their parameters, in the configuration file:

```
;######### ACQUISITION GLOBAL CONFIG ############

;#implementation: Acquisition algorithm selection for this channel:
Acquisition_1C.implementation=GPS_L1_CA_PCPS_Acquisition
;#dump: Enable or disable the acquisition internal data file logging [true] or [false]

;#filename: Log path and filename
Acquisition_1C.dump_filename=./acq_dump.dat
```

```
;#item_type: Type and resolution for each of the signal samples. Use only gr_complex in this version.
Acquisition_1C.item_type=gr_complex
;#coherent_integration_time_ms: Signal block duration for the acquisition signal detection [ms]
Acquisition_1C.coherent_integration_time_ms=1
;#threshold: Acquisition threshold
Acquisition_1C.threshold=2.5
;#pfa: Acquisition false alarm probability. This option overrides the threshold option.
Acquisition_1C.pfa=0.0001
;#doppler_max: Maximum expected Doppler shift [Hz]
Acquisition_1C.doppler_max=5000
;#doppler_step: Doppler step in the grid search [Hz]
Acquisition_1C.doppler_step=250
```

1.6.3.2 Tracking

When a satellite is declared present, the parameters estimated by the acquisition module are then fed to the receiver tracking module, which represents the second stage of the signal processing unit, aiming to perform a local search for accurate estimates of code delay and carrier phase, and following their eventual variations.

Again, a class hierarchy consisting of a TrackingInterface class and subclasses implementing algorithms provides a way of testing different approaches, with full access to their parameters. Check DllPllTrackingAdapter for an example of an adapter from a DLL/PLL tracking block to TrackingInterface, and dll_pll_veml_tracking for an example of a signal processing block implementation. There are also available some useful classes and functions for signal tracking; take a look at Correlator, lock_detectors.h, tracking_discriminators.h or tracking_2nd_DLL_filter.h.

The source code of all the available tracking algorithms is located at:

```
|-gnss-sdr
|---src
|-----algorithms
|-------tracking
|---------adapters          <- Adapters of the processing blocks to a TrackingInterface
|---------gnuradio_blocks   <- Signal processing blocks implementation
|---------libs              <- libraries of tracking objects (e.g. correlators, discriminators, and so on)
```

The user can select a given implementation for the algorithm to be used in all the tracking blocks, as well as its parameters, in the configuration file:

```
;######### TRACKING GLOBAL CONFIG ############

;#implementation: Selected tracking algorithm
Tracking_1C.implementation=GPS_L1_CA_DLL_PLL_Tracking
;#item_type: Type and resolution for each of the signal samples.

;#early_late_space_chips: correlator early-late space [chips].
Tracking_1C.early_late_space_chips=0.5;
```

1.6.3.3 Decoding of the navigation message

Most of GNSS signal links are modulated by a navigation message containing the time the message was transmitted, orbital parameters of satellites (also known as ephemeris) and an almanac (information about the general system health, rough orbits of all satellites in the network as well as data related to error correction). Navigation data bits are structured in words, pages, subframes, frames and superframes. Sometimes, bits corresponding to a single parameter are spread over different words, and values extracted from different frames are required for proper decoding. Some words are for synchronization purposes, others for error control an others contain actual information. There are also error control mechanisms, from parity checks to forward error correction (FEC) encoding and interleaving, depending on the system.

The common interface is TelemetryDecoderInterface. Check TelemetryDecoderAdapter for an example of an adapter from a telemetry decoder block to TelemetryDecoderInterface, and gps_l1_ca_telemetry_decoder_gs for an actual implementation of a signal processing block. Configuration example:

```
;######### TELEMETRY DECODER CONFIG ############
TelemetryDecoder_1C.implementation=GPS_L1_CA_Telemetry_Decoder
TelemetryDecoder_1C.dump=false
```

See the Reference Documents for more information about the signal format.

1.6.4 Observables

GNSS systems provide different kinds of observations. The most commonly used are the code observations, also called pseudoranges. The *pseudo* comes from the fact that on the receiver side the clock error is unknown and thus the measurement is not a pure range observation. High accuracy applications also use the carrier phase observations, which are based on measuring the difference between the carrier phase transmitted by the GNSS satellites and the phase of the carrier generated in the receiver. Both observables are computed from the outputs of the tracking module and the decoding of the navigation message. This module collects all the data provided by every tracked channel, aligns all received data into a coherent set, and computes the observables.

The common interface is ObservablesInterface.

Configuration example:

```
;######### OBSERVABLES CONFIG ############
Observables.implementation=Hybrid_Observables

;#dump: Enable or disable the Observables internal binary data file logging [true] or [false]
Observables.dump=false

;#dump_filename: Log path and filename.
Observables.dump_filename=./observables.dat
```

1.6.5 Computation of Position, Velocity and Time

GNSS-SDR provides a module that can compute standalone position fixes and an opt-in NTRIP-corrected RTK solution for dual-band GPS (L1 C/A + L2C or L1 C/A + L5), Galileo (E1 + E5a), and combined GPS+Galileo receivers. It can also store observables and navigation data for use with tools such as GNSSTk or gLAB.

The common interface is PvtInterface. For instance, in order to use the implementation RTKLIB_PVT, add to the configuration file:

```
;######### PVT CONFIG ############
PVT.implementation=RTKLIB_PVT

;#nmea_dump_filename: NMEA log path and filename
PVT.nmea_dump_filename=./gnss_sdr_pvt.nmea;

;#flag_nmea_tty_port: Enable or disable the NMEA log to a serial TTY port (Can be used with real hardware or v
PVT.flag_nmea_tty_port=true;

;#nmea_dump_devname: serial device descriptor for NMEA logging
PVT.nmea_dump_devname=/dev/pts/4

;#dump: Enable or disable the PVT internal binary data file logging [true] or [false]
PVT.dump=false
```

This implementation allows tuning of the following parameters:

```
PVT.implementation=RTKLIB_PVT
PVT.positioning_mode=Single      ; options: Single, Static, Kinematic, PPP_Static, PPP_Kinematic
PVT.satellite_ephemeris=Broadcast ; options: Broadcast, SBAS

PVT.iono_model=Broadcast         ; options: OFF, Broadcast, SBAS, Iono-Free-LC, Estimate_STEC, IONEX
PVT.trop_model=Saastamoinen      ; options: OFF, Saastamoinen, SBAS, Estimate_ZTD, Estimate_ZTD_Grad
PVT.rinex_version=2              ; options: 2 or 3
PVT.output_rate_ms=100           ; Period in [ms] between two PVT outputs
PVT.display_rate_ms=500          ; Position console print (std::out) interval [ms].
PVT.nmea_dump_filename=./gnss_sdr_pvt.nmea ; NMEA log path and filename
PVT.flag_nmea_tty_port=false     ; Enables the NMEA log to a serial TTY port
PVT.nmea_dump_devname=/dev/pts/4 ; serial device descriptor for NMEA logging
PVT.flag_rtcm_server=true        ; Enables an outbound raw TCP server dispatching generated RTCM messages
PVT.ntrip_client_enabled=false   ; Enables inbound RTCM corrections from an NTRIP caster (physical base or VRS
PVT.flag_rtcm_tty_port=false     ; Enables the RTCM log to a serial TTY port
PVT.rtcm_dump_devname=/dev/pts/1 ; serial device descriptor for RTCM logging
PVT.rtcm_tcp_port=2101
PVT.rtcm_MT1019_rate_ms=5000

PVT.rtcm_MT1077_rate_ms=1000
```

1.6.5.1 Dual-band RTK through NTRIP

The `RTKLIB_PVT` implementation can obtain base-station corrections from an NTRIP caster. This feature is opt-in: `PVT.ntrip_client_enabled` defaults to `false`, and no caster connection is attempted while it is disabled. Per constellation, and freely combined, the receiver may run GPS L1 C/A (`1C`) alone or together with one of L2C (`2S`) or L5 (`L5`), Galileo E1 (`1B`) alone or together with E5a (`5X`), and BeiDou B1C (`1D`, single-frequency); a second band without its first band, both GPS second bands at once, and other signals are rejected. Single-band sets run single-frequency RTK, which is viable on the short effective baselines of VRS services and benefits from combining both constellations. `PVT.navigation_system` must match the enabled constellations exactly ($$ 1 $$ GPS, $$ 8 $$ Galileo, $$ 32 $$ BeiDou, or their sum), and the number of frequency slots is derived from the channel set ($$ 1 $$ for single-band sets; $$ 2 $$ with GPS L2C; $$ 3 $$ whenever L5 or E5a is involved, since both occupy the third RTKLIB slot). GPS L5 and Galileo E5a share the same center frequency, and BeiDou B1C shares the GPS L1 / Galileo E1 center, so the combined GPS L1+L5 / Galileo E1+E5a dual-frequency receiver needs only two RF channels, and a single-frequency GPS+Galileo+BeiDou receiver needs one. Select `Static` for a stationary rover or `Kinematic` for a moving rover; other positioning modes are rejected when the NTRIP client is enabled.

An NTRIP-corrected rover configuration can include:

```
Channels_1C.count=8
Channels_2S.count=8

PVT.implementation=RTKLIB_PVT
PVT.positioning_mode=Kinematic
PVT.num_bands=2
```

```
PVT.navigation_system=1

PVT.ntrip_client_enabled=true
PVT.ntrip_caster_address=caster.example.org
PVT.ntrip_caster_port=2101
PVT.ntrip_mountpoint=EXAMPLE_MOUNTPOINT
PVT.ntrip_username=example_user
PVT.ntrip_password=
PVT.ntrip_password_env=GNSS_SDR_NTRIP_PASSWORD
PVT.ntrip_version=2
PVT.ntrip_tls_enabled=false
PVT.ntrip_inactivity_timeout_ms=10000
PVT.ntrip_reconnect_interval_ms=10000
PVT.ntrip_max_correction_age_s=5.0
PVT.ntrip_station_id=0
PVT.ntrip_fallback_to_single=true
PVT.ntrip_send_gga=true
PVT.ntrip_gga_period_ms=10000
```

The caster address, mountpoint, username, password, and password-environment variable name default to empty strings; the remaining defaults are those shown above, except that `PVT.ntrip_client_enabled` defaults to `false`. Set either `PVT.ntrip_password` or `PVT.ntrip_password_env`, never both. The latter names an environment variable from which GNSS-SDR reads the password and avoids placing the password in the configuration file. Station ID `0` accepts any station; otherwise, set the expected RTCM station ID. Setting `PVT.ntrip_reconnect_interval_ms=0` disables operational reconnect attempts; the one immediate v2-to-v1 compatibility retry still runs and is not counted as an automatic reconnect.

The correction stream must provide an RTCM 3 base position message 1005 or 1006 and observation messages carrying at least each satellite's first band: for GPS, L1 (with L2 or L5 when available) as messages 1002 or 1004 or as MSM4 through MSM7 (1074 through 1077); for Galileo, E1 (with E5a when available) as MSM4 through MSM7 (1094 through 1097); for BeiDou, B1C as MSM4 through MSM7 (1124 through 1127), where the decoder prefers B1C over B1I when the base broadcasts both in the shared first slot. Base satellites providing only the first band contribute single-band double differences; the second band of the receiver's pair is used whenever both sides supply it. Corrections older than `PVT.ntrip_max_correction_age_s` are not used. Enabling this client forces a separate internal single-point solver for receiver-clock correction, independently of the RTK solver. With `PVT.ntrip_fallback_to_single=true`, the receiver reports an explicitly labeled `SOLQ_SINGLE` solution while corrections are unavailable, incomplete, or stale; it does not label that fallback as an RTK solution.

This client sends an NTRIP version 2 HTTP/1.1 request by default and accepts a legacy v1 reply on that connection. If the fully-sent v2 exchange closes or times out before receiving any response bytes, or returns HTTP 400, 501, or 505, it opens one fresh connection and retries using the v1 HTTP/1.0 request. Once selected, v1 is retained for operational reconnects until the client is stopped and started again. DNS, TCP, TLS, and partial-write failures before the request is sent do not trigger a downgrade; `PVT.ntrip_version=1` forces v1 from the first connection. Setting `PVT.ntrip_tls_enabled=true` encrypts both attempts with TLS 1.2 or newer, validating the caster certificate against the system CA store and its host name. Without TLS, Basic authentication only encodes credentials; it does not encrypt them, so use a trusted network or a suitable secure tunnel, and prefer `PVT.ntrip_password_env` over a password stored in a file. VRS and nearest-station mountpoints that require rover GGA reports are supported: with `PVT.ntrip_send_gga=true` (the default), the client periodically sends an NMEA GGA sentence derived from the receiver's current position estimate, every `PVT.ntrip_gga_period_ms` (10 s by default, accepted range 1 s to 24 hours). No GGA is sent before the receiver produces its first position solution; the single-point bootstrap fix is enough for the caster to start serving the virtual station. Set `PVT.ntrip_send_gga=false` if the rover position must not be reported to the caster; physical-base mountpoints work either way.

`PVT.flag_rtcm_server` is unrelated to the NTRIP correction client. It controls an outbound raw TCP server for RTCM messages generated by GNSS-SDR; it neither connects to a caster nor supplies corrections to the RTK solver. The outbound server and inbound NTRIP client can be enabled independently.

For legacy SBAS/EGNOS L1 positioning, use GPS L1 observation channels together with at least one SBAS L1 telemetry channel, and set `PVT.satellite_ephemeris=SBAS`, `PVT.iono_model=SBAS`, and `PVT.trop_model=SBAS`. EGNOS currently augments GPS L1; RTKLIB excludes a satellite when the selected SBAS stream has no valid correction for it. This path provides non-safety-critical Open Service positioning and does not compute protection levels or implement a Safety-of-Life receiver.

1.7 About the software license

GNSS-SDR is released under the General Public License (GPL) v3, thus securing practical usability, inspection, and continuous improvement by the research community, allowing the discussion based on tangible code and the analysis of results obtained with real signals. The GPL implies that:

- Copies may be distributed free of charge or for money, but the source code has to be shipped or provided free of charge (or at cost price) on demand. The receiver of the source code has the same rights meaning he can share copies free of charge or resell.
- The licensed material may be analyzed or modified.
- Modified material may be distributed under the same licensing terms but **do not** have to be distributed.

That means that modifications only have to be made available to the public if distribution happens. So it is perfectly fine to take the GNSS-SDR source code, modify it heavily and use it in a not distributed application / library. This is how companies like Google can run their own patched versions of Linux for example.

But what this also means is that non-GPL code cannot use GPL code. This means that you cannot modify / use GNSS-SDR, blend it with non-GPL code, and make money with the resulting software. You cannot distribute the resulting software under a non-disclosure agreement or contract. Distributors under the GPL also grant a license for any of their patents practiced by the software, to practice those patents in GPL software. You can sell a device that runs with GNSS-SDR, but if you distribute the code, it has to remain under GPL.

1.9 Ok, now what?

In order to start using GNSS-SDR, you may want to populate `gnss-sdr/data` folder (or anywhere else on your system) with raw data files. By "raw data" we mean the output of a Radio Frequency front-end's Analog-to-↩ Digital converter. GNSS-SDR needs signal samples already in baseband or in passband, at a suitable intermediate frequency (on the order of MHz). Prepare your configuration file, and then you are ready for going to the `gnss-sdr/install` folder, running `./gnss-sdr`, and see how the file is processed. Please ask the Developer Team for a signal sample if you need one, and they will do their best ;-)

Another interesting option is working in real-time with a RF front-end. We provide drivers for UHD-compatible hardware (see Signal Source) and for some DVB-T USB dongles. Start with a low number of channels and then increase it in order to test how many channels your processor can handle in real-time.

You can find more information at the **GNSS-SDR Documentation page** or directly asking to the **GNSS-SDR Developers mailing list**.

You are also very welcome to contribute to the project, there are many ways to **participate in GNSS-SDR**. If you need some special feature not yet implemented, the Developer Team would love to be hired for developing it. Please do not hesitate to **contact them**.

Enjoy GNSS-SDR!

The Developer Team.

2.2 Other Standards

2.2.1 RINEX

The final output of a navigation receiver is usually its position, speed or other related physical quantities. However, the calculation of those quantities are based on a series of measurements from one or more satellite constellations. Although receivers calculate positions in real time, in many cases it is interesting to store intermediate measures for later post-processing. RINEX is the standard format that allows the management and disposal of the measures generated by a receiver, as well as their off-line processing by a multitude of applications.

- The most common version at present is **RINEX: The Receiver Independent Exchange Format Version 2.12**, which enables storage of measurements from pseudorange, carrier-phase and Doppler systems for GPS, GLONASS, Galileo along with data from EGNOS and WAAS satellite based augmentation systems (SBAS).

- The most recent version is **RINEX: The Receiver Independent Exchange Format Version 3.03** published in July, 2015. It includes Galileo and improves the handling of multi-constellation data files.

- There is also available the **RINEX Extensions to Handle Clock Information**, published in September, 2010.

2.2.2 NMEA

The National Marine Electronics Association released the NMEA 0183 Interface Standard, which defines electrical signal requirements, data transmission protocol and time, and specific sentence formats for a 4800-baud serial data bus. The standard is available for purchase.

2.2.3 KML

KML is an XML language focused on geographic visualization, including annotation of maps and images. Geographic visualization includes not only the presentation of graphical data on the globe, but also the control of the user's navigation in the sense of where to go and where to look. Google submitted KML (formerly Keyhole Markup Language) to the Open Geospatial Consortium (OGC) to be evolved within the OGC consensus process with the following goal: KML Version 2.2 has been adopted as an OGC implementation standard.

2.2.4 C++ Standards

The C++ programming language is standardized by the International Organization for Standardization (ISO), with the latest standard version ratified and published by ISO in December 2017 as ISO/IEC 14882:2017 (informally known as C++17). The list of supported C++ standards (the highest available is automatically selected by the CMake script):

2.2.5 Positioning protocols in wireless communication networks

Cellular industry location standards first appeared in the late 1990s, with the 3rd generation partnership project (3GPP) radio resource location services protocol (RRLP) technical specification 44.031 positioning protocol for GSM networks. Today, RRLP is the de facto standardized protocol to carry GNSS assistance data to GNSS-enabled mobile devices, and the term "3GPP specification" now covers all GSM (including GPRS and EDGE), W-CDMA and LTE (including LTE-A) specifications. Precisely, the label "LTE-A" is applied to networks compliant with LTE Release 10 and beyond, which fulfill the requirements issued by the International Telecommunication Union Radiocommunication Sector (ITU-R) in the global standard for international mobile telecommunications (IMT Advanced, also referred to as 4G) access technologies. Chapter 3

Signal model

3.1 GNSS signal model

This page describes signals transmitted by GNSS space vehicles. Signal models are mathematical representations of the electromagnetic waves that are exciting the receiver's antenna. The current induced by those waves is then amplified, filtered and downconverted to a suitable frequency (can be at some intermediate frequency or directly to baseband), and then converted to 0s and 1s by the Analog-to-Digital Converter (ADC). That is the job of the Radio Frequency front-end, which at its output delivers a stream of digital samples. Those samples constitute the input of a software receiver, so for GNSS-SDR the signal models described below can be seen as *the rules of the game*.

GNSS' space vehicles are modern versions of lighthouses, but with better visibility. Each satellite is a reference point, and if we know our distance to several reference points, we can compute our location, just as mariners do when they see a couple of lighthouses. For each in-view satellite i of system s, we can write:

$$\rho_i = \sqrt{\left(x_i^{\text{Tx}} - x\right)^2 + \left(y_i^{\text{Tx}} - y\right)^2 + \left(z_i^{\text{Tx}} - z\right)^2} + c\Delta t^{(s)} + \sigma_e, \tag{3.1}$$

where $\left(x_i^{\text{Tx}}, y_i^{\text{Tx}}, z_i^{\text{Tx}}\right)$ is the satellite's position (known from the navigation message), (x, y, z) the receiver's position, and σ_e gathers other sources of error. Since the receiver needs to estimate its own 3D position (three spatial unknowns) and its clock deviation with respect to the satellites' time basis, at least $3 + N_s$ satellites must be seen by the receiver at the same time, where N_s is the number of different navigation systems available (in-view) at a given time. Each received satellite signal, once synchronized and demodulated at the receiver, defines one equation such as the one defined above, forming a set of nonlinear equations that can be solved algebraically by means of the `Bancroft algorithm` or numerically, resorting to multidimensional Newton-Raphson and weighted least square methods. When *a priori* information is added we resort to Bayesian estimation, a problem that can be solved recursively by a Kalman filter or any of its variants. The problem can be further expanded by adding other unknowns (for instance, parameters of ionospheric and tropospheric models), sources of information from other systems, mapping information, and even motion models of the receiver. In the design of multi-constellation GNSS receivers, the vector of unknowns can also include the receiver clock offset with respect to each system in order to take advantage of a higher number of in-view satellites and using them jointly in the navigation solution, therefore increasing accuracy.

The `analytic representation` of a signal received from a GNSS satellite can be generically expressed as

$$r(t) = \alpha(t) s_T\left(t - \tau(t)\right) e^{-j2\pi f_d(t)} e^{j2\pi f_c t} + n(t)\ , \tag{3.2}$$

where $\alpha(t)$ is the amplitude, $s_T(t)$ is the complex baseband transmitted signal, $\tau(t)$ is the time-varying delay, $f_d(t) = f_c\tau(t)$ is the Doppler shift, f_c is the carrier frequency, and $n(t)$ is a noise term. These signals arrive to the Earth's surface at extremely low power (e.g. -158.5 dBW for GPS L1 C/A-code, -157 dBW for Galileo E1), well below the noise floor. In order to estimate its distances to satellites, the receiver must correlate time-aligned replicas of the corresponding pseudorandom code with the incoming signal, in a process called *despreading* that

provides processing gain only to the signal of interest. After a coarse and fine estimation stages of the synchronization parameters (usually known as acquisition and tracking, respectively), signal processing output is in form of *observables*:

i) the pseudorange (code) measurement, equivalent to the difference of the time of reception (expressed in the time frame of the receiver) and the time of transmission (expressed in the time frame of the satellite) of a distinct satellite signal; and optionally

ii) the carrier-phase measurement, actually being a measurement on the beat frequency between the received carrier of the satellite signal and a receiver-generated reference frequency. Carrier phase measurements are ambiguous, in the sense that the integer number of carrier wavelengths between satellite and the receiver's antenna is unknown. Techniques such as Least-square AMBiguity Decorrelation Approach (LAMBDA) or Multi Carrier Ambiguity Resolution (MCAR) can be applied to resolve such ambiguity and provide an accurate estimation of the distance between the satellite and the receiver.

Then, depending on the required accuracy, the navigation solution can range from pseudorange-only, computationally low demanding, and limited accuracy least squares methods to sophisticated combinations of code and phase observables at different frequencies for high demanding applications such as surveying, geodesy, and geophysics.

Next sections provide brief descriptions of the space segment of different GNSSs and their broadcast signal structures accessible by civilians.

3.1.1 Global Positioning System (GPS) signal in space

The Global Positioning System (GPS) is a space-based radio-navigation system owned by the United States Government (USG) and operated by the United States Air Force (USAF). GPS provides positioning and timing services to military and civilian users on a continuous, worldwide basis. Two GPS services are provided: the Precise Positioning Service (PPS), available primarily to the military of the United States and its allies, and the Standard Positioning Service (SPS) open to civilian users.

- **GPS L1**. Defined at **Interface Specification IS-GPS-200 Revision M**, this band is centered at $f_{\text{GPS L1}} = 1575.42$ MHz. The complex baseband transmitted signal can be written as

$$s_T^{(\text{GPS L1})}(t) = e_{L1I}(t) + j e_{L1Q}(t) \ , \tag{3.3}$$

with

$$e_{L1I}(t) = \sum_{l=-\infty}^{\infty} D_{\text{NAV}}\Big[[l]_{204600}\Big] \oplus C_{\text{P(Y)}}\Big[|l|_{L_{\text{P(Y)}}}\Big] p(t - lT_{c,\text{P(Y)}}) \ , \tag{3.4}$$

$$e_{L1Q}(t) = \sum_{l=-\infty}^{\infty} D_{\text{NAV}}\Big[[l]_{20460}\Big] \oplus C_{\text{C/A}}\Big[|l|_{1023}\Big] p(t - lT_{c,\text{C/A}}) \ , \tag{3.5}$$

where $\oplus$ is the exclusive-or operation (modulo-2 addition), $|l|_L$ means l modulo L, $[l]_L$ means the integer part of $\frac{l}{L}$, D_{NAV} is the GPS navigation message bit sequence, transmitted at 50 bps, $T_{c,\text{P(Y)}} = \frac{1}{10.23}$ μs, $T_{c,\text{C/A}} = \frac{1}{1.023}$ μs, $L_{\text{P(Y)}} = 6.1871 \cdot 10^{12}$, and $p(t)$ is a rectangular pulse of a chip-period duration centered at $t = 0$ and filtered at the transmitter. According to the chip rate, the binary phase-shift keying modulations in the equations above are denoted as BPSK(10) and BPSK(1), respectively. The precision P codes (named Y codes whenever the anti-spoofing mode is activated, encrypting the code and thus denying non-↩ U.S. military users) are sequences of 7 days in length. Regarding the modernization plans for GPS, it is worthwhile to mention that there is a new civilian-use signal planned, called L1C and defined at **Interface Specification IS-GPS-800 Revision H**, to be broadcast on the same L1 frequency that currently contains the C/A signal. The L1C is available with first Block III launch. The implementation provides C/A code to ensure backward compatibility.

- **GPS L2C**. Defined at **Interface Specification IS-GPS-200 Revision M**, is only available on Block IIR-M and subsequent satellite blocks. Centered at $f_{\text{GPS L2}} = 1227.60$ MHz, the signal structure is the same than in (eq:GPSL1}), with the precision code in the In-phase component, just as in (eq:L1CAI}) but with an optional presence of the navigation message D_{NAV}. For the Quadrature-phase component, three options are defined:

$$e_{L2CQ}(t) = \sum_{l=-\infty}^{\infty} D_{\text{CNAV}}\left[[l]_{10230}\right] \oplus \left(C_{\text{CL}}\left[|l|_{L_{\text{CL}}}\right] p_{1/2}\left(t - lT_{c,L2C}\right) + \right. \tag{3.6}$$

$$\left. + C_{\text{CM}}\left[|l|_{L_{\text{CM}}}\right] p_{1/2}\left(t - \left(l + \frac{3}{4}\right) T_{c,L2C}\right)\right), \tag{3.7}$$

$$e_{L2CQ}(t) = \sum_{l=-\infty}^{\infty} D_{\text{NAV}}\left[[l]_{20460}\right] \oplus C_{\text{C/A}}\left[|l|_{1023}\right] p\left(t - lT_{c,\text{C/A}}\right), \text{ or} \tag{3.8}$$

$$e_{L2CQ}(t) = \sum_{l=-\infty}^{\infty} C_{\text{C/A}}\left[|l|_{1023}\right] p(t - lT_{c,\text{C/A}}), \tag{3.9}$$

where $T_{c,L2C} = \frac{1}{511.5}$ ms and $p_{1/2}(t)$ is a rectangular pulse of half chip-period duration, thus time-multiplexing both codes. The civilian long code C_{CL} is $L_{\text{CL}} = 767250$ chips long, repeating every 1.5 s, while the civilian moderate code C_{CM} is $L_{\text{CL}} = 10230$ chips long and its repeats every 20 ms. The CNAV data is an upgraded version of the original NAV navigation message, containing higher precision representation and nominally more accurate data than the NAV data. It is transmitted at 25 bps with forward error correction (FEC) encoding, resulting in 50 sps.

- **GPS L5**. The GPS L5 link, defined at **Interface Specification IS-GPS-705 Revision H**, is only available in Block IIF (first satellite launched on May, 2010) and subsequent satellite blocks. Centered at $f_{\text{GPS L5}} = 1176.45$ MHz, this signal in space can be written as:

$$s_T^{(\text{GPS L5})}(t) = e_{L5I}(t) + je_{L5Q}(t), \tag{3.10}$$

$$e_{L5I}(t) = \sum_{m=-\infty}^{+\infty} C_{nh_{10}}\left[|m|_{10}\right] \oplus D_{\text{CNAV}}\left[[m]_{10}\right] \oplus \tag{3.11}$$

$$\oplus \sum_{l=1}^{102300} C_{L5I}\left[|l|_{10230}\right] p(t - mT_{c,nh} - lT_{c,L5}),$$

$$e_{L5Q}(t) = \sum_{m=-\infty}^{+\infty} C_{nh_{20}}\left[|m|_{20}\right] \oplus \sum_{l=1}^{102300} C_{L5Q}\left[|l|_{10230}\right] \cdot$$

$$\cdot\, p(t - mT_{c,nh} - lT_{c,L5}), \tag{3.12}$$

where $T_{c,nh} = 1$ ms and $T_{c,L5} = \frac{1}{10.23}$ μs, thus defining a BPSK(10) modulation. Both L5I and L5Q contain synchronization sequences. \end{itemize}

3.1.2 GLONASS signal in space

The nominal baseline constellation of the Russian Federation's Global Navigation Satellite System (GLONASS) comprises 24 GLONASS-M satellites that are uniformly deployed in three roughly circular orbital planes at an inclination of 64.8^o to the equator. The altitude of the orbit is $19,100$ km. The orbit period of each satellite is 11 hours, 15 minutes, and 45 seconds. The orbital planes are separated by 120^o right ascension of the ascending node. Eight satellites are equally spaced in each plane with 45^o argument of latitude. Moreover, the orbital planes have an argument of latitude displacement of 15^o relative to each other.

GLONASS civil signal-in-space is defined at **Interface Control Document. Navigational radiosignal in bands L1, L2. Edition 5.1**. This system makes use of a frequency-division multiple access (FDMA) signal structure, transmitting in two bands: $f_{GLOL1}^{(k)} = 1602 + k \cdot 0.5625$ MHz and $f_{GLOL2}^{(k)} = 1246 + k \cdot 0.4375$ MHz, where $k \in \{-7, -6, \cdots, 5, 6\}$ is the channel number. Satellites in opposite points of an orbit plane transmit signals on equal frequencies, as these satellites will never be in view simultaneously by a ground-based user.

- **GLONASS L1**. Two kind of signals are transmitted: a standard precision (SP) and an obfuscated high precision (HP) signal. The complex baseband transmitted signal can be written as

$$s_T^{(\text{GLO L1})}(t) = e_{L1I}(t) + j e_{L1Q}(t) \, , \tag{3.13}$$

with BPSK(5) and BPSK(0.5) modulations:

$$e_{L1I}(t) = \sum_{l=-\infty}^{\infty} D_{\text{GNAV}}\Big[[l]_{102200}\Big] \oplus C_{\text{HP}}\Big[|l|_{L_{\text{HP}}}\Big] p(t - lT_{c,\text{HP}}) \, , \tag{3.14}$$

$$e_{L1Q}(t) = \sum_{l=-\infty}^{\infty} D_{\text{GNAV}}\Big[[l]_{10220}\Big] \oplus C_{\text{SP}}\Big[|l|_{511}\Big] p(t - lT_{c,\text{SP}}) \, , \tag{3.15}$$

where $T_{c,\text{HP}} = \frac{1}{5.11}$ μs, $T_{c,\text{SP}} = \frac{1}{0.511}$ μs, and $L_{\text{HP}} = 3.3554 \cdot 10^7$. The navigation message D_{GNAV} is transmitted at 50 bps. Details of its content and structure, as well as the generation of the C_{SP} code, can be found at the ICD. The usage of the HP signal should be agreed with the Russian Federation Defense Ministry, and no more details have been disclosed.

- **GLONASS L2**. Beginning with the second generation of satellites, called GLONASS-M and first launched in 2001, a second civil signal is available using the same SP code than the one in the L1 band.

The use of FDMA techniques, in which the same code is used to broadcast navigation signals on different frequencies, and the placement of civil GLONASS transmissions on frequencies close to 1600 MHz, well above the GPS L1 band, have complicated the design of combined GLONASS/GPS receivers, particularly low-cost equipment for mass-market applications. Future plans of modernization are intended to increase compatibility and interoperability with other GNSS, and include the addition of a code-division multiple access (CDMA) structure, and possibly binary offset carrier (BOC) modulation, beginning with the third civil signal in the L3 band ($1197.648 - 1212.255$ MHz). Russia is implementing the new signals on the next-generation GLONASS-K satellites, with a first prototype successfully launched into orbit on February 26, 2011.

3.1.3 Galileo signal in space

The nominal Galileo constellation comprises a total of 27 operational satellites (plus 3 active spares), that are evenly distributed among three orbital planes inclined at 56^o relative to the equator. There are nine operational satellites per orbital plane, occupying evenly distributed orbital slots. Three additional spare satellites (one per orbital plane) complement the nominal constellation configuration. The Galileo satellites are placed in quasi-circular Earth orbits with a nominal semi-major axis of about $30,000$ km and an approximate revolution period of 14 hours. The Control segment full infrastructure will be composed of $30 - 40$ sensor stations, 3 control centers, 9 Mission Uplink stations, and 5 TT&C stations.

Galileo's Open Service is defined at **Signal In Space Interface Control Document. Ref: OS SIS ICD, Issue 2.0**, where the following signal structures are specified:

- **Galileo E1**. This band, centered at $f_{\text{Gal E1}} = 1575.420$ MHz and with a reference bandwidth of 24.5520 MHz, uses the so-called composite binary offset carrier CBOC(6,1, $\frac{1}{11}$) modulation, defined in baseband as:

$$s_T^{(\text{Gal E1})}(t) = \frac{1}{\sqrt{2}}\Big(e_{E1B}(t) \left(\alpha sc_A(t) + \beta sc_B(t)\right) + \tag{3.16}$$

$$- e_{E1C}(t) \left(\alpha sc_A(t) - \beta sc_B(t)\right) \Big) \, , \tag{3.17}$$

where the subcarriers $sc(t)$ are defined as

$$sc_A(t) = \text{sign}\Big(\sin(2\pi f_{s,E1A} t) \Big) \, , \tag{3.18}$$

$$sc_B(t) = \text{sign}\Big(\sin(2\pi f_{s,E1B} t) \Big) \, , \tag{3.19}$$

and $f_{s,E1A} = 1.023$ MHz, $f_{s,E1B} = 6.138$ MHz are the subcarrier rates, $\alpha = \sqrt{\frac{10}{11}}$, and $\beta = \sqrt{\frac{1}{11}}$. Channel B contains the I/NAV type of navigation message, $D_{\text{I/NAV}}$, intended for Safety-of-Life (SoL) services:

$$e_{E1B}(t) = \sum_{l=-\infty}^{+\infty} D_{\text{I/NAV}}\Big[[l]_{4092}\Big] \oplus C_{E1B}\Big[|l|_{4092}\Big] p(t - lT_{c,E1B}). \tag{3.20}$$

In case of channel C, it is a pilot (dataless) channel with a secondary code, forming a tiered code:

$$\begin{aligned} e_{E1C}(t) = &\sum_{m=-\infty}^{+\infty} C_{E1Cs}\Big[|m|_{25}\Big] \oplus \sum_{l=1}^{4092} C_{E1Cp}\Big[l\Big] \cdot \\ &\cdot p(t - mT_{c,E1Cs} - lT_{c,E1Cp}) \ , \end{aligned} \tag{3.21}$$

with $T_{c,E1B} = T_{c,E1Cp} = \frac{1}{1.023}$ μs and $T_{c,E1Cs} = 4$ ms. The C_{E1B} and C_{E1Cp} primary codes are pseudorandom memory code sequences defined at Annex C of OS SIS ICD. The binary sequence of the secondary code C_{E1Cs} is 00111000000010101101100 10. This band also contains another component, Galileo E1A, intended for the Public Regulated Service (PRS). It uses a BOC(15,2.5) modulation with cosine-shaped subcarrier $f_{s,E1A} = 15.345$ MHz and $T_{c,E1A} = \frac{1}{2.5575}$ μs. The PRS spreading codes and the structure of the navigation message have not been made public.

- **Galileo E6**. Intended for the Commercial Service and centered at $f_{\text{Gal E6}} = 1278.750$ MHz, this band provides pilot and data components

$$s_T^{(\text{Gal E6})}(t) = \frac{1}{\sqrt{2}} \left(e_{E6B}(t) - e_{E6C}(t)\right) \ , \tag{3.22}$$

$$\begin{aligned} e_{E6B}(t) = &\sum_{m=-\infty}^{+\infty} D_{\text{C/NAV}}\Big[[l]_{5115}\Big] \oplus C_{E6B}\Big[|l|_{L_{E6B}}\Big] \cdot \\ &\cdot p(t - lT_{c,E6}), \end{aligned} \tag{3.23}$$

$$\begin{aligned} e_{E6C}(t) = &\sum_{m=-\infty}^{+\infty} C_{E6Cs}\Big[|m|_{100}\Big] \oplus \sum_{l=1}^{L_{E6C}} C_{E6Cp}\Big[l\Big] \cdot \\ &\cdot p(t - mT_{c,E6s} - lT_{c,E6p}), \end{aligned} \tag{3.24}$$

where $D_{\text{C/NAV}}$ is the C/NAV navigation data stream, which is modulated with the encrypted ranging code C_{E6B} with chip period $T_{c,E6} = \frac{1}{5.115}$ μs, thus being a BPSK(5) modulation. Codes C_{E6B} and primary codes C_{E6Cs} and their respective lengths, L_{E6B} and L_{E6C}, have not been published. The secondary codes for the pilot component, C_{E6Cs}, are available at the OS SIS ICD. The receiver reference bandwidth for this signal is 40.920 MHz. This band also contains another component, Galileo E6A, intended for PRS.

- **Galileo E5**. Centered at $f_{\text{Gal E5}} = 1191.795$ MHz and with a total bandwidth of 51.150 MHz, its signal structure deserves some analysis. The AltBOC modulation can be generically expressed as

$$s^{\text{AltBOC}}(t) = x_1(t)v^*(t) + x_2(t)v(t) \ , \tag{3.25}$$

where $v(t) = \frac{1}{\sqrt{2}} \left(\text{sign}\left(\cos(2\pi f_s t)\right) + j\text{sign}\left(\sin(2\pi f_s t)\right)\right)$ is the single side-band subcarrier, f_s is the subcarrier frequency, $(\cdot)^*$ stands for the conjugate operation, and $x_1(t)$ and $x_2(t)$ are QPSK signals. The resulting waveform does not exhibit constant envelope. In case of Galileo, the need for high efficiency of the satellites' onboard High Power Amplifier (HPA) has pushed a modification on the signal in order to make it envelope-constant and thus use the HPA at saturation. This can be done by adding some inter-modulation products to the expression above, coming up with the following definition:

$$\begin{aligned} s_T^{(\text{Gal E5})}(t) = &e_{E5a}(t)ssc_s^*(t) + e_{E5b}(t)ssc_s(t) + \\ &+ \bar{e}_{E5a}(t)ssc_p^*(t) + \bar{e}_{E5b}(t)ssc_p(t) \ , \end{aligned} \tag{3.26}$$

where the single and product side-band signal subcarriers are

$$ssc_s(t) = sc_s(t) + jsc_s\left(t - \frac{T_s}{4}\right), \tag{3.27}$$

$$ssc_p(t) = sc_p(t) + jsc_p\left(t - \frac{T_s}{4}\right), \tag{3.28}$$

and

$$e_{E5a}(t) = e_{E5aI}(t) + je_{E5aQ}(t), \tag{3.29}$$
$$e_{E5b}(t) = e_{E5bI}(t) + je_{E5bQ}(t), \tag{3.30}$$
$$\bar{e}_{E5a}(t) = \bar{e}_{E5aI}(t) + j\bar{e}_{E5aQ}(t), \tag{3.31}$$
$$\bar{e}_{E5b}(t) = \bar{e}_{E5bI}(t) + j\bar{e}_{E5bQ}(t), \tag{3.32}$$
$$\bar{e}_{E5aI}(t) = e_{E5aQ}(t)e_{E5bI}(t)e_{E5bQ}(t), \tag{3.33}$$
$$\bar{e}_{E5aQ}(t) = e_{E5aI}(t)e_{E5bI}(t)e_{E5bQ}(t), \tag{3.34}$$
$$\bar{e}_{E5bI}(t) = e_{E5bQ}(t)e_{E5aI}(t)e_{E5aQ}(t), \tag{3.35}$$
$$\bar{e}_{E5bQ}(t) = e_{E5bI}(t)e_{E5aI}(t)e_{E5aQ}(t). \tag{3.36}$$

The signal components are defined as

$$e_{E5aI}(t) = \sum_{m=-\infty}^{+\infty} C_{E5aIs}\Big[|m|_{20}\Big] \oplus \sum_{l=1}^{10230} C_{E5aIp}\Big[l\Big] \oplus \tag{3.37}$$
$$\oplus\, D_{\text{F/NAV}}\Big[[l]_{204600}\Big]\, p(t - mT_{c,E5s} - lT_{c,E5p}), \tag{3.38}$$
$$e_{E5aQ}(t) = \sum_{m=-\infty}^{+\infty} C_{E5aQs}\Big[|m|_{100}\Big] \oplus \sum_{l=1}^{10230} C_{E5aQp}\Big[l\Big] \cdot \tag{3.39}$$
$$\cdot\, p(t - mT_{c,E5s} - lT_{c,E5p}), \tag{3.40}$$
$$e_{E5bI}(t) = \sum_{m=-\infty}^{+\infty} C_{E5bIs}\Big[|m|_{4}\Big] \oplus \sum_{l=1}^{10230} C_{E5aIp}\Big[l\Big] \oplus \tag{3.41}$$
$$\oplus\, D_{\text{I/NAV}}\Big[[l]_{40920}\Big]\, p(t - mT_{c,E5s} - lT_{c,E5p}), \tag{3.42}$$
$$e_{E5bQ}(t) = \sum_{m=-\infty}^{+\infty} C_{E5bQs}\Big[|m|_{100}\Big] \oplus \sum_{l=1}^{10230} C_{E5bQp}\Big[l\Big] \cdot \tag{3.43}$$
$$\cdot\, p(t - mT_{c,E5s} - lT_{c,E5p}), \tag{3.44}$$

where $T_{c,E5s} = 1$ ms and $T_{c,E5p} = \frac{1}{10.23}$ μs. Channel A contains the F/NAV type of navigation message, $D_{\text{F/NAV}}$, intended for the Open Service. The I/NAV message structures for the E5bI and E1B signals use the same page layout. Only page sequencing is different, with page swapping between both components in order to allow a fast reception of data by a dual frequency receiver. The single subcarrier $sc_s(t)$ and the product subcarrier $sc_p(t)$ are defined as:

$$sc_s(t) = \frac{\sqrt{2}}{4}\text{sign}\left(\cos\left(2\pi f_s t - \frac{\pi}{4}\right)\right) + \tag{3.45}$$
$$+ \frac{1}{2}\text{sign}\Big(\cos\left(2\pi f_s t\right)\Big) +$$
$$+ \frac{\sqrt{2}}{4}\text{sign}\left(\cos\left(2\pi f_s t + \frac{\pi}{4}\right)\right), \tag{3.46}$$

$$sc_p(t) = -\frac{\sqrt{2}}{4}\text{sign}\left(\cos\left(2\pi f_s t - \frac{\pi}{4}\right)\right) + \tag{3.47}$$
$$+ \frac{1}{2}\text{sign}\Big(\cos\left(2\pi f_s t\right)\Big) +$$
$$- \frac{\sqrt{2}}{4}\text{sign}\left(\cos\left(2\pi f_s t + \frac{\pi}{4}\right)\right), \tag{3.48}$$

with a subcarrier frequency of $f_s = 15.345$ MHz, thus defining an AltBOC(15,10) modulation. The QPSK(10) signal $e_{E5a}(t)$ defined above is shifted to $f_{\text{Gal E5a}} \doteq f_{\text{Gal E5}} - f_s = 1176.450$ MHz, while $e_{E5b}(t)$ is shifted to $f_{\text{Gal E5b}} \doteq f_{\text{Gal E5}} + f_s = 1207.140$ MHz. Thus, we can bandpass filter around $f_{\text{Gal E5a}}$ and get a good approximation of a QPSK(10) signal, with very low energy components of $e_{E5b}(t)$, $\bar{e}_{E5a}(t)$, and $\bar{e}_{E5b}(t)$:

$$s_T^{(\text{Gal E5a})}(t) \simeq e_{E5aI}(t) + je_{E5aQ}(t). \tag{3.49}$$

The same applies to $e_{E5b}(t)$, allowing an independent reception of two QPSK(10) signals and thus requiring considerably less bandwidth than the processing of the whole E5 band.

Author

This header file contains the interface to an abstract class for signal sources. Since all its methods are virtual, this class cannot be instantiated directly, and a subclass can only be instantiated directly if all inherited pure virtual methods have been implemented by that class or a parent class.

10.2.5 core_receiver

Namespaces

- namespace block_factory

  Class that produces all kinds of GNSS blocks.

Classes

- class Concurrent_Map< Data >

  This class implements a thread-safe std::map.
- class Concurrent_Queue< Data >

  This class implements a thread-safe std::queue.
- class ControlThread

  This class represents the main thread of the application, so the name is ControlThread. This is the GNSS Receiver Control Plane: it connects the flowgraph, starts running it, and while it does not stop, reads the control messages generated by the blocks, processes them, and applies the corresponding actions.
- class FileConfiguration

  This class is an implementation of the interface ConfigurationInterface.
- class GNSSFlowgraph

  This class represents a GNSS flow graph.
- class InMemoryConfiguration

This class is an implementation of the interface ConfigurationInterface.

- class SatelliteVisibility

  Opt-in acquisition search classification: visible, excluded, or unknown. Healthy satellites above the search mask are preferred; unknowns are searched less often. Banned PRNs are omitted, and tracking can override exclusion. Tick() refreshes on reference, fix, navigation-data, position, interval, or expiry changes. Expired data returns satellites to the unknown pool. Disabled by default (GNSS-SDR.enable_visibility_aware_search).

- class TcpCmdInterface

Functions

- std::vector< std::pair< int, Gnss_Satellite > > compute_visible_satellites (const std::shared_ptr< PvtInterface > &pvt_ptr, const gtime_t &gps_gtime, const arma::vec &r_eb_e, double elevation_mask_deg, std::vector< std::pair< int, Gnss_Satellite > > *below_mask_out=nullptr, double almanac_max_age_s=std::numeric_limits< double >::infinity(), double *seconds_until_next_expiry_out=nullptr, const std::set< std::pair< std::string, uint32_t > > *only_prns=nullptr, bool glonass_strict_health=true)

  Return healthy GPS/Galileo/BeiDou/GLONASS/QZSS satellites above the mask. Prefer fresh ephemeris over almanac. BeiDou selects the closest orbit (ties: DNAV, CNAV1, CNAV2); B-CNAV supports IGSO/MEO only. Unhealthy satellites are excluded, not unknown; Galileo uses E1B health.

10.2.5.1 Detailed Description

Classes for the core GNSS receiver.

10.2.5.2 Function Documentation

10.2.5.2.1 compute_visible_satellites()

```
std::vector< std::pair< int, Gnss_Satellite > > compute_visible_satellites (
            const std::shared_ptr< PvtInterface > & pvt_ptr,
            const gtime_t & gps_gtime,
            const arma::vec & r_eb_e,
            double elevation_mask_deg,
            std::vector< std::pair< int, Gnss_Satellite > > * below_mask_out = nullptr,
            double almanac_max_age_s = std::numeric_limits< double >::infinity(),
            double * seconds_until_next_expiry_out = nullptr,
            const std::set< std::pair< std::string, uint32_t > > * only_prns = nullptr,
            bool glonass_strict_health = true)
```

Return healthy GPS/Galileo/BeiDou/GLONASS/QZSS satellites above the mask. Prefer fresh ephemeris over almanac. BeiDou selects the closest orbit (ties: DNAV, CNAV1, CNAV2); B-CNAV supports IGSO/MEO only. Unhealthy satellites are excluded, not unknown; Galileo uses E1B health.

Parameters

gps_gtime	GPST query epoch; also resolves truncated navigation weeks.
r_eb_e	receiver ECEF position (m).
elevation_mask_deg	search mask (deg), independent of PVT.elevation_mask.
below_mask_out	optional output for satellites at/below the mask or unhealthy.
almanac_max_age_s	maximum absolute almanac age (s); infinity disables it. Ephemeris age limits use RTKLIB's per-system MAXDTOE* constants.
seconds_until_next_expiry_out	optional time to earliest classified-data expiry; infinity if nothing was classified.
only_prns	optional (system, PRN) filter; requires unchanged position/time.
glonass_strict_health	also reject the Bn MSB; In always marks unhealthy.

Returns

(floor(elevation) in degrees, satellite) pairs, highest elevation first.

Functions

- Agnss_Ref_Location parse_agnss_ref_location (const std::string &ref_location_str)

Single parsing point for ControlThread and SatelliteVisibility.

- constexpr uint32_t qzss_l1cb_prn_to_nominal_prn (uint32_t prn)

  Maps QZSS L1 C/B PRNs to the PRN carrying the satellite's nominal PNT signals. L1 C/B is broadcast with a dedicated PRN (203-206), but the transmitting satellite is identified by the PRN of its nominal signals (RINEX 4.00, Table 6: QZSS PRN to RINEX Satellite Identifier): 203->196 (J04), 204->197 (J05), 205->200 (J08), 206->201 (J09). Returns the input PRN unchanged if it is not an L1 C/B alias; in particular, PRN 202 (J10) broadcasts L1 C/B under its own PRN.

            const double alpha[9],
            double freq_hz)
```
Compute BDGIM slant ionospheric delay [m] at carrier frequency freq_hz.

Parameters

time_mjd	Modified Julian Date (days) of the computation epoch
lat_rad	User geodetic latitude [rad]
lon_rad	User geodetic longitude [rad]
az_rad	Satellite azimuth [rad]
el_rad	Satellite elevation [rad]
alpha	Broadcast BDGIM parameters alpha1..alpha9 [TECu]

freq_hz	Carrier frequency [Hz]

10.2.6.5.4 gps_ref_week_from_config()

```
int32_t gps_ref_week_from_config (
            const std::string & observation_date,
            bool pre_2009_file)
```

Derives the reference GPS week number used to resolve the GPS mod-1024 week-number rollover when post-processing recorded signal files.

Parameters

observation_date	Value of the GNSS-SDR.observation_date configuration option: approximate date of the signal capture, in "YYYY-MM-DD" or "YYYY" format. An empty string means "not set".
pre_2009_file	Value of the deprecated GNSS-SDR.pre_2009_file flag.

Returns

The full GPS week number of the observation date. Each mod-1024 broadcast week number is then resolved to the 1024-week era that places it closest to this reference week (see adjgpsweek()). Returns 0 if neither option is set, which keeps the default behavior of deriving the era from the system clock. If only the deprecated flag is set, it returns week 1535 (mid-point of the 1999-2019 era), which reproduces the legacy fixed +1024 week adjustment, and a one-time deprecation notice is printed.

10.2.6.5.5 parse_agnss_ref_location()

```
Agnss_Ref_Location parse_agnss_ref_location (
            const std::string & ref_location_str)  [inline]
```

Parses GNSS-SDR.AGNSS_ref_location ("lat,lon" or "lat lon", degrees). valid is false if the string is empty or not a plausible WGS84 position. Single parsing point for ControlThread and SatelliteVisibility.
Definition at line 74 of file agnss_ref_location.h.

10.2.6.5.6 parse_agnss_ref_utc_time()

            bool * malformed_year = nullptr,
            bool * malformed_format = nullptr)  [inline]
```

Parses GNSS-SDR.AGNSS_ref_utc_time ("DD/MM/YYYY HH:MM:SS", UTC). An empty string is not an error: the host's current time is returned, marked valid. malformed_year and malformed_format (both optional) tell why a non-empty string was rejected. Single parsing point for ControlThread and SatelliteVisibility.

```
uint32_t qzss_l1cb_prn_to_nominal_prn (
            uint32_t prn)  [constexpr]
```

Maps QZSS L1 C/B PRNs to the PRN carrying the satellite's nominal PNT signals. L1 C/B is broadcast with a dedicated PRN (203-206), but the transmitting satellite is identified by the PRN of its nominal signals (RINEX 4.00, Table 6: QZSS PRN to RINEX Satellite Identifier): 203->196 (J04), 204->197 (J05), 205->200 (J08), 206->201 (J09). Returns the input PRN unchanged if it is not an L1 C/B alias; in particular, PRN 202 (J10) broadcasts L1 C/B under its own PRN.

10.8.2.4.1 alm_to_rtklib()

```
alm_t alm_to_rtklib (
            const Gps_Almanac & gps_alm,
            int ref_week = 0)
```
Converts almanac data to RTKLIB's alm_t format.

Parameters

ref_week	Current GPS week, used to resolve the truncated almanac week (WNa: 8 bits for GPS, 2 bits for Galileo) to the closest full week so that alm.toa is an absolute epoch, as eph_to_rtklib() does for ephemeris. 0 (default) uses WNa as-is; only valid for callers that never propagate the orbit (e.g. unit tests checking unrelated fields).

References alm_to_rtklib().
Referenced by alm_to_rtklib().

10.8.2.4.2 eph_to_rtklib()

```
geph_t eph_to_rtklib (
            const Glonass_Gnav_Ephemeris & glonass_gnav_eph,
            const Glonass_Gnav_Utc_Model & gnav_clock_model,
            bool glonass_strict_health = true)
```
Transforms a Glonass_Gnav_Ephemeris to its RTKLIB counterpart.

Parameters

glonass_gnav_eph	GLONASS GNAV Ephemeris structure
gnav_clock_model	GLONASS GNAV UTC model (for the GLONASST to GPST conversion)
glonass_strict_health	when true (default), the MSB of the Bn word also marks the satellite as unhealthy; when false, only the In flag is used

Returns

Ephemeris structure for RTKLIB parsing

10.8.2.4.3 glonass_almanac_epoch()

```
gtime_t glonass_almanac_epoch (
            const Glonass_Gnav_Almanac & almanac)
```

Absolute GPST epoch of a GLONASS almanac (N_4/N_A calendar day plus t_lambda_n_A, which is given in MSK = UTC+3).

Returns

Zero gtime_t when the broadcast date is unavailable or invalid.

References glonass_almanac_epoch().
Referenced by glonass_almanac_epoch().

10.8.2.4.4 glonass_gnav_is_healthy()

```

            const Glonass_Gnav_Ephemeris & glonass_gnav_eph,
            bool glonass_strict_health = true)
```

Broadcast health of a GLONASS satellite according to its GNAV ephemeris.

Parameters

glonass_gnav_eph	GLONASS GNAV Ephemeris structure
glonass_strict_health	when true (default), the MSB of the Bn word also marks the satellite as unhealthy; when false, only the In flag is used

Returns

true if the satellite does not report a malfunction

Functions

- void secure_clear_ntrip_credentials (Pvt_Conf ∗conf) noexcept

  Scrubs the NTRIP credential fields of a Pvt_Conf copy ahead of its destruction (the Secure_String fields wipe themselves on release, but a long-lived copy should drop its secrets as soon as they are consumed). Single home of the credential field list.
- bool ntrip_text_has_space_or_control (const std::string &text)

  True when the text contains whitespace or control characters — the character rule shared by the credential validation and the adapter's environment-variable-name check.
- Ntrip_Rtcm_Client_Config make_ntrip_rtcm_client_config (const Pvt_Conf &conf)

  Builds the NTRIP client configuration from the PVT configuration — the single home of the field mapping, shared by the adapter's validation and by the PVT block's client construction. The mountpoint is stored normalized; validate() and the transport-path builder normalize again defensively for directly-built configurations.
- bool ntrip_rtk_is_entry_band (const Ntrip_Rtk_Signal &signal)

  The entry band of every constellation occupies RTKLIB's first slot, so "first band" is band_slot == 0 by definition — a fact, not a column that could drift from the slot assignment.
- const std::array< Ntrip_Rtk_Signal, 6 > & ntrip_rtk_signals ()

- std::string ntrip_rtk_supported_sets_description ()

  Human-readable list of the supported per-system channel sets, derived from the table for the adapter's rejection message.

```

RTKLIB slot of a satellite system's second band given the enabled channels. QZSS rides the GPS bands. When no second band of the system is enabled, the constellation's canonical second slot is returned (Galileo/BeiDou: 2, both anticipate slot-2 signals; GPS/QZSS: 1) so unsupported slots can be cleared.

10.8.6.4.6 ntrip_rtk_signals()

```
const std::array< Ntrip_Rtk_Signal, 6 > & ntrip_rtk_signals ()  [inline]
```

The signal table. A function-local static keeps the header buildable as C++11 (an inline variable would need C++17) while still providing a single instance. Keep each constellation's second bands ordered by preference: with more than one enabled (a configuration the adapter rejects today), ntrip_rtk_second_band_slot() picks the first match.

            const Signal_Enabled_Flags & enabled)  [inline]
```

```
float carrier_lock_detector (

```
A carrier lock detector.
The Carrier Phase Lock Detector block uses the estimate of the cosine of twice the carrier phase error is given by

$$C2\phi = \frac{NBD}{NBP}, \tag{10.1}$$

where $NBD = (\sum_{i=0}^{N-1} |Im(Pc(i))|)^2 + (\sum_{i=0}^{N-1} |Re(Pc(i))|)^2$, $NBP = \sum_{i=0}^{N-1} Im(Pc(i))^2 - \sum_{i=0}^{N-1} Re(Pc(i))^2$, and $Pc(i)$ is the prompt correlator output for the sample index i. 10.13.4.4.4 cn0_m2m4_estimator()

```
float cn0_m2m4_estimator (
            const gr_complex * Prompt_buffer,
            int length,
            float coh_integration_time_s)
```

cn0_m2m4_estimator is a Carrier-to-Noise (CN0) estimator based on the Second- and Fourth-Order Moments Method (M2M4)
Signal-to-Noise (SNR) (ρ) estimator using the Moments Method:

$$\hat{\rho} = \frac{\sqrt{2\hat{M}_2^2 - \hat{M}_4}}{\hat{M}_2 - \sqrt{2\hat{M}_2^2 - \hat{M}_4}}, \tag{10.2}$$

where $\hat{M}_2 = \frac{1}{N}\sum_{k=0}^{K-1}|P[k]|^2$, $\hat{M}_4 = \frac{1}{K}\sum_{k=0}^{K-1}|P[k]|^4$, $|\cdot|$ is the absolute value, and $P[k]$ is the prompt correlator output for the sample index k.
The SNR value is converted to CN0 [dB-Hz] taking into account the coherent integration time, using the following formula:

$$CN0_{dB} = 10 * log(\hat{\rho}) - 10 * log(T_{int}), \tag{10.3}$$

where T_{int} is the coherent integration time, in seconds.

```

cn0_svn_estimator is a Carrier-to-Noise (CN0) estimator based on the Signal-to-Noise Variance (SNV) estimator
Signal-to-Noise (SNR) (ρ) estimator using the Signal-to-Noise Variance (SNV) estimator:

$$\hat{\rho} = \frac{\hat{P}_s}{\hat{P}_n} = \frac{\hat{P}_s}{\hat{P}_{tot} - \hat{P}_s}, \tag{10.4}$$

where $\hat{P}_s = \left(\frac{1}{N}\sum_{i=0}^{N-1}|Re(Pc(i))|\right)^2$ is the estimation of the signal power, $\hat{P}_{tot} = \frac{1}{N}\sum_{i=0}^{N-1}|Pc(i)|^2$ is the estimator of the total power, $|\cdot|$ is the absolute value, $Re(\cdot)$ stands for the real part of the value, and $Pc(i)$ is the prompt correlator output for the sample index i.
The SNR value is converted to CN0 [dB-Hz], taking into account the coherent integration time, using the following formula:

$$CN0_{dB} = 10 * log(\hat{\rho}) - 10 * log(T_{int}), \tag{10.5}$$

where T_{int} is the coherent integration time, in seconds.

12.5.1 Detailed Description

This abstract class represents an interface to an acquisition GNSS block.
Abstract class for acquisition algorithms. Since all its methods are virtual, this class cannot be instantiated directly, and a subclass can only be instantiated directly if all inherited pure virtual methods have been implemented by that class or a parent class.
Definition at line 50 of file acquisition_interface.h.

12.19.1 Detailed Description

Bayesian_estimator is an estimator of noise characteristics (i.e. mean, covariance).
Bayesian_estimator is an estimator which performs estimation of noise characteristics from a sequence of identically and independently distributed (IID) samples of a stationary stochastic process by way of Bayesian inference using conjugate priors. The posterior distribution is assumed to be Gaussian with mean \mathbf{\mu} and covariance \hat{\mathbf{C}}, which has a conjugate prior given by a normal-inverse-Wishart distribution with parameters \mathbf{\mu}_{0}, \kappa_{0}, \nu_{0}, and \mathbf{\Psi}.

            const float * current_1ms,

```
Soft preamble detection statistic on 1 ms prompt samples.
current_1ms points to BEIDOU_CNAV2_PREAMBLE_MS samples at a candidate frame start, previous_1ms (optional) to the samples one frame (3 s) earlier. With C the correlation with the preamble spread by the data secondary code and E the sample energy, it returns max(|C1| / sqrt(E1), |C1 + C2| / sqrt(E1 + E2)). The result does not depend on the input scale and is about |N(0,1)| on noise. The single-frame term keeps detection working across a carrier polarity flip between the two frames.

12.68 HistogramBitSynchronizer::Config Struct Reference

  Time interval between successive calls to update(), in milliseconds.
- int min_events_for_lock

  Minimum number of detected transition events required before lock evaluation.
- double dominance_ratio

  Required dominance ratio of the winning histogram bin.
- double runner_up_margin

  Required normalized margin between the best and second-best bins.
- int stable_best_required

Required stability of the dominant histogram bin (consecutive evaluations).

- float min_prompt_mag

  Minimum magnitude of the prompt correlator output.

- int transition_window_epochs

  Number of prompt epochs averaged on each side of a candidate edge.

- double transition_confidence

  Minimum normalized transition confidence required for a histogram vote.

- int tentative_events_required

  Number of fresh phase-matching events required after tentative lock.

- bool use_phase_dot_detector

  Select the transition detection method.

12.68.1 Detailed Description

Configuration parameters for HistogramBitSynchronizer.
These parameters define the bit period, the update cadence, the lock criteria, and the transition detection method.
Definition at line 44 of file bit_synchronizer.h.

12.68.2 Constructor & Destructor Documentation

12.68.2.1 Config()

```
HistogramBitSynchronizer::Config::Config () [inline]
```

Definition at line 169 of file bit_synchronizer.h.

12.68.3 Member Data Documentation

12.68.3.1 bit_period_ms

```
int HistogramBitSynchronizer::Config::bit_period_ms
```

Navigation data bit period in milliseconds.
This is the nominal duration of one navigation data bit.
Definition at line 51 of file bit_synchronizer.h.

12.68.3.2 dominance_ratio

```
double HistogramBitSynchronizer::Config::dominance_ratio
```

Required dominance ratio of the winning histogram bin.
Lock requires the most frequent histogram bin to be sufficiently dominant:

$$\text{dominance_ratio} = \frac{\text{best_bin_count}}{\text{total_detected_events}}$$

Guidance:

- Values near 0.5 may lock faster but increase false-lock probability.
- Values closer to 1.0 are conservative and require a clearly dominant phase.

Definition at line 85 of file bit_synchronizer.h.

12.68.3.3 epoch_ms

```
int HistogramBitSynchronizer::Config::epoch_ms
```

Time interval between successive calls to update(), in milliseconds.
This should match the minimum integration interval (epoch) produced by the tracking loop and used to generate the provided prompt correlator output.
Definition at line 59 of file bit_synchronizer.h.

12.68.3.4 min_events_for_lock

`int HistogramBitSynchronizer::Config::min_events_for_lock`
Minimum number of detected transition events required before lock evaluation.
The histogram is built from detected candidate transitions. Lock decisions are not attempted until at least this many events have been accumulated.
Trade-offs:

- Larger values increase robustness against false locks but increase time-to-lock.
- Smaller values reduce time-to-lock but increase sensitivity to noise/spurious transitions.

Definition at line 71 of file bit_synchronizer.h.

12.68.3.5 min_prompt_mag

`float HistogramBitSynchronizer::Config::min_prompt_mag`
Minimum magnitude of the prompt correlator output.
Candidate transition detection is suppressed when $|P| <$ min_prompt_mag, where P is the prompt correlator output.
Use this to avoid counting unreliable transitions when tracking quality is poor or the prompt output is dominated by noise.
Definition at line 116 of file bit_synchronizer.h.

12.68.3.6 runner_up_margin

`double HistogramBitSynchronizer::Config::runner_up_margin`
Required normalized margin between the best and second-best bins.
The margin is computed as (best_count - second_best_count) / total_events. This prevents lock when two candidate phases have similar support.
Definition at line 93 of file bit_synchronizer.h.

12.68.3.7 stable_best_required

`int HistogramBitSynchronizer::Config::stable_best_required`
Required stability of the dominant histogram bin (consecutive evaluations).
Even if the dominance ratio is met, the algorithm requires that the same histogram bin remains dominant for this many consecutive event-driven lock evaluations before declaring lock. Evaluations without a newly detected transition do not count toward this requirement.
This helps prevent locking on transient peaks caused by noise or short-lived disturbances.
Definition at line 105 of file bit_synchronizer.h.

12.68.3.8 tentative_events_required

`int HistogramBitSynchronizer::Config::tentative_events_required`
Number of fresh phase-matching events required after tentative lock.
Once the histogram satisfies its dominance, runner-up margin, and stability requirements, this many subsequent transition events must occur in the same phase bin before lock is declared. Winner stability and tentative validation advance concurrently; they are not applied as serial waiting periods.
Definition at line 144 of file bit_synchronizer.h.

12.68.3.9 transition_confidence

`double HistogramBitSynchronizer::Config::transition_confidence`
Minimum normalized transition confidence required for a histogram vote.
Confidence combines the phase inversion between the pre-edge and post-edge prompt averages with their internal coherence. It lies in the range [-1, 1], with values near 1 indicating a clean polarity inversion.
Definition at line 134 of file bit_synchronizer.h.

12.68.3.10 transition_window_epochs

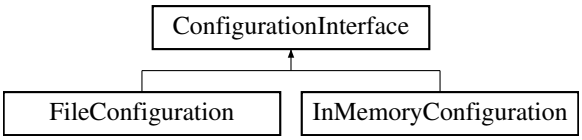
`int HistogramBitSynchronizer::Config::transition_window_epochs`
Number of prompt epochs averaged on each side of a candidate edge.
A transition is evaluated after this many prompt epochs have been observed on both sides of the candidate boundary. Values larger than one improve rejection of isolated noisy prompt inversions at the cost of a short detection delay.
Definition at line 125 of file bit_synchronizer.h.

12.68.3.11 use_phase_dot_detector

`bool HistogramBitSynchronizer::Config::use_phase_dot_detector`
Select the transition detection method.
If true (recommended), compares coherent prompt averages immediately before and after each candidate boundary. A transition is detected when:

$$-\frac{\Re\{A_{after}A^*_{before}\}}{|A_{after}||A_{before}|}$$

combined with the internal coherence of each averaging window exceeds Config::transition_confidence.
This method is insensitive to constant carrier phase rotations and rejects isolated prompt inversions and ambiguous samples near a candidate boundary.
If false, uses a simpler sign-change detector on the real part:



- A candidate transition is detected when sign(Re(P_k)) != sign(Re(P_{k-1})).

This assumes the prompt output is already aligned with the data bit polarity (i.e., stable PLL lock and correct navigation bit polarity mapping).

12.69.1 Detailed Description

This abstract class represents an interface to configuration parameters.
The interface defines an accessor method that gets a parameter name as input and returns the value of this parameter, a string, as output. Property names are defined here. This is an abstract class for interfaces. Since all its methods are virtual, this class cannot be instantiated directly, and a subclass can only be instantiated directly if all inherited pure virtual methods have been implemented by that class or a parent class.

  Evaluate the PCPS grid for `bins` Doppler bins.
- size_t device_bytes () const

  Number of bytes allocated on the device by this instance.

12.82.1 Detailed Description

Batched PCPS grid evaluation on a CUDA device.
Typical usage (mirrors pcps_acquisition):

1. Construct with the FFT geometry of the acquisition block.
2. set_doppler_wipeoffs() whenever the Doppler grid changes.
3. set_fft_codes() whenever the local code (PRN) changes.
4. compute_grid() once per dwell; the magnitude grid is written to the host rows supplied by the caller, so the existing CPU peak-search and statistics code can be reused unchanged.

Each instance owns a CUDA stream, so several channels acquiring at the same time run their grids concurrently on the device.
Definition at line 52 of file cuda_pcps_engine.h.

12.82.2 Member Enumeration Documentation

12.82.2.1 GridId

```
enum CudaPcpsEngine::GridId :  int
```

Identifier of the Doppler grid uploaded with set_doppler_wipeoffs().

Enumerator

MAIN_GRID	Coarse grid (doppler_min .. doppler_max, doppler_step).
STEP2_GRID	Fine grid used when make_two_steps=true.

Definition at line 56 of file cuda_pcps_engine.h.

12.82.3 Constructor & Destructor Documentation

12.82.3.1 CudaPcpsEngine()

```
CudaPcpsEngine::CudaPcpsEngine (
            uint32_t fft_size,
            uint32_t effective_fft_size,
            uint32_t max_doppler_bins,
            int device = -1)
```

Parameters

fft_size	Length of the FFTs (input vector length).
effective_fft_size	Number of code-phase cells written per Doppler bin (fft_size, or fft_size/2 when bit_↩ transition_flag is set).
max_doppler_bins	Upper bound on the number of bins in any grid.
device	CUDA device ordinal, or -1 for the current/default device.

References CudaPcpsEngine().

12.82.4 Member Function Documentation

12.82.4.1 compute_grid()

```
bool CudaPcpsEngine::compute_grid (
            const std::complex< float > * in,
            GridId grid,
```

```
            uint32_t bins,
            uint32_t offset,
            bool accumulate,
            float *const * magnitude_out)
```

Evaluate the PCPS grid for `bins` Doppler bins.
For every bin k: mag_k[i] (+)= | IFFT(FFT(in .* w_k) .* C)[offset + i] |^2, with C = conj(FFT(code)), i in [0, effective_fft_size).

Parameters

in	Input samples (fft_size complex values, host memory).
grid	Which wipe-off grid to use.
bins	Number of Doppler bins to compute (<= bins uploaded for `grid`).
offset	First sample of the output window (fft_size/2 when bit_transition_flag).
accumulate	false: overwrite the output rows; true: add to their current contents (non-coherent integration across dwells). Accumulation is kept on the device, so the host rows are always the full running sum.
magnitude_out	Array of `bins` host pointers, each with room for effective_fft_size floats.

12.82.4.2 device_bytes()

```
size_t CudaPcpsEngine::device_bytes () const
```

Number of bytes allocated on the device by this instance.

12.82.4.3 device_name()

```

True when construction succeeded and the engine can be used.

12.82.4.5 last_error()

```

Human-readable description of the last error (empty if none).

12.82.4.6 set_doppler_wipeoffs()

            GridId grid,
            const std::complex< float > *const * wipeoffs,
            uint32_t bins)
```

Upload the Doppler wipe-off carriers for one grid. Uploads complete before returning; the caller may reuse the host rows.

Parameters

grid	MAIN_GRID or STEP2_GRID.
wipeoffs	Array of `bins` host pointers, each pointing at fft_size complex samples.
bins	Number of Doppler bins (<= max_doppler_bins).

12.82.4.7 set_fft_codes()

```
bool CudaPcpsEngine::set_fft_codes (
            const std::complex< float > * fft_codes)
```

Upload conj(FFT(local code)), fft_size elements. The upload completes before returning; the caller may reuse fft_codes.

Public Member Functions

- ~dll_pll_veml_tracking_fpga ()

  Destructor.
- void set_channel (uint32_t channel, const std::string &device_io_name)

  Set the channel number and configure some multicorrelator parameters.
- void set_gnss_synchro (Gnss_Synchro *p_gnss_synchro)

  This function is used with two purposes: 1 -> To set the gnss_synchro 2 -> A set_gnss_synchro command with a valid PRN is received when the system is going to run acquisition with that PRN. We can use this command to pre-initialize tracking parameters and variables before the actual acquisition process takes place. In this way we minimize the latency between acquisition and tracking once the acquisition has been made.
- void start_tracking ()

  This function starts the tracking process.
- void stop_tracking ()

  This function sets a flag that makes general_work to stop in order to finish the tracking process.

12.112.1 Detailed Description

This class is an implementation of the interface ConfigurationInterface.
Derived from ConfigurationInterface, this class implements an interface to a configuration file. This implementation has a text file as the source for the values of the parameters. The file is in the INI format, containing sections and pairs of names and values. For more information about the INI format, see https://en.wikipedia.org/↩wiki/INI_file

12.114.1 Detailed Description

Base class to file-oriented SignalSourceBase GNSS blocks.
This class supports the following properties:
.filename - the path to the input file

- may be overridden by the -signal_source or -s command-line arguments

.samples - number of samples to process (default 0)

- if not specified or 0, read the entire file; otherwise stop after that many samples

.sampling_frequency - the frequency of the sampled data (samples/second)
.item_type - data type of the samples (default "short")
.header_size - the size of a prefixed header to skip in "samples" (default 0)
.seconds_to_skip - number of seconds of lead-in data to skip over (default 0)
.enable_throttle_control - whether to stop reading if the upstream buffer is full (default false)
.repeat - whether to rewind and continue at end of file (default false)
(probably abstracted to the base class)
.dump - whether to archive input data
.dump_filename - if dumping, path to file for output

The purpose of this is to have the option to allow the FPGA to compensate for a possible deviation between the nominal value of the PRN code length and the measured PRN code length in the PRN immediately following the start of the coherent integration only. If this option is not used then write the same value to first_length_secondary_code and next_length_secondary_code.

This class adapts a gnuradio gr_freq_xlating_fir_filter designed with pm_remez.
Construct a FIR filter with the given taps and a composite frequency translation that shifts intermediate_freq_ down to zero Hz. The frequency translation logically comes before the filtering operation.
See Parks-McClellan FIR filter design, https://en.wikipedia.org/wiki/Parks-McClellan_↩filter_design_algorithm Calculates the optimal (in the Chebyshev/minimax sense) FIR filter impulse response given a set of band edges, the desired response on those bands, and the weight given to the error in those bands.

```
Stops any channel whose decoded satellite is already tracked, on the same signal, by another channel with higher C/N0. The stopped channel's assignment returns to the search pool and the channel is re-dispatched.
GLONASS channels are assigned a frequency channel and only learn their orbital slot from the navigation message, so a false lock can be relabelled as a satellite another channel already tracks; duplicate observations of one satellite break the PVT solution.

12.177.3.15 UpdateVisibilityReference()

            const std::array< float, 3 > & LLH)

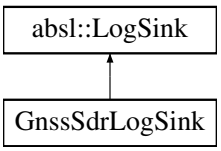
12.177.3.17 wait()

```
void GNSSFlowgraph::wait ()
```



Wait for a flowgraph to complete.
Flowgraphs complete when either (1) all blocks indicate that they are done, or (2) after stop() has been called to request shutdown.

12.215.1 Detailed Description

Histogram-based navigation data bit synchronizer.
Definition at line 35 of file bit_synchronizer.h.

12.215.2 Constructor & Destructor Documentation

12.215.2.1 HistogramBitSynchronizer()

```
HistogramBitSynchronizer::HistogramBitSynchronizer (
            const Config & cfg)  [inline], [explicit]
```

Construct a histogram bit synchronizer with the provided configuration.
Initializes internal counters and allocates the histogram with bins() entries, all set to zero.

Parameters

cfg	Configuration parameters.

Definition at line 193 of file bit_synchronizer.h.
References bins().

12.215.3 Member Function Documentation

12.215.3.1 bins()

```
int HistogramBitSynchronizer::bins () const
```

Return the number of histogram bins.
Derived from the bit period and epoch duration, e.g.: bins = bit_period_ms / epoch_ms

Returns

Number of histogram bins.

Referenced by HistogramBitSynchronizer().

12.215.3.2 edge_phase()

```
int HistogramBitSynchronizer::edge_phase () const  [inline]
```

Get the estimated bit edge phase bin.
The edge phase is expressed as an integer histogram bin index in the range [0, bins()-1] when locked. The interpretation is "which epoch phase within the bit period is most likely to contain a navigation bit transition."

Returns

Estimated edge phase bin index, or -1 if not locked.

Definition at line 259 of file bit_synchronizer.h.

12.215.3.3 epochs_until_next_edge()

```
int HistogramBitSynchronizer::epochs_until_next_edge () const
```

Return the number of epochs until the next predicted navigation bit edge.
When the synchronizer is locked, this function computes the forward distance (in epochs) from the most recently processed epoch to the next epoch that is aligned with the estimated bit-edge phase.
The result is expressed modulo the bit period and has the following meaning:

- 0 : the current epoch corresponds to the predicted start of a new navigation bit
- $>$0 : number of epochs remaining until the next bit boundary

The computation is based on the internal epoch counter advanced by update(), assuming that update() is called once per epoch with a constant cadence equal to Config::epoch_ms.
If the synchronizer is not locked, or if the configuration yields an invalid number of bins, this function returns -1.

Returns

Number of epochs until the next predicted bit edge, or -1 if not locked or if the bit period configuration is invalid.

12.215.3.4 get_epoch_count()

```
std::int64_t HistogramBitSynchronizer::get_epoch_count () const  [inline]
```

Total number of epochs processed by update().
This counter increments once per call to update(), regardless of whether a transition is detected or whether tracking_quality_ok is true.

Returns

Total processed epochs.

Definition at line 310 of file bit_synchronizer.h.

12.215.3.5 get_histogram()

```
const std::vector< int > & HistogramBitSynchronizer::get_histogram () const  [inline]
```

Access the internal histogram (read-only).
Each entry counts how many detected candidate transitions occurred at the corresponding phase bin within the bit period.

Returns

Reference to the histogram vector.

Definition at line 293 of file bit_synchronizer.h.

12.215.3.6 get_total_events()

```
std::int64_t HistogramBitSynchronizer::get_total_events () const  [inline]
```

Total number of detected transition events accumulated into the histogram.

Returns

Total detected events.

Definition at line 300 of file bit_synchronizer.h.

12.215.3.7 is_edge_epoch()

```
bool HistogramBitSynchronizer::is_edge_epoch (
            std::int64_t k) const
```

Predict whether a given epoch index corresponds to a bit edge.
For a given epoch index `k` (0-based), this function returns true when `k` is aligned with the currently estimated edge phase (i.e., the predicted transition epoch), and false otherwise.
If not locked, this always returns false.

Parameters

k	Epoch index (0-based, consistent with the caller's epoch counting).

Returns

True if `k` is the predicted edge epoch; false otherwise.

12.215.3.8 locked()

```
bool HistogramBitSynchronizer::locked () const  [inline]
```

Query whether the synchronizer has achieved lock.

Returns

True if lock has been declared, false otherwise.

Definition at line 248 of file bit_synchronizer.h.

12.215.3.9 reset()

```
void HistogramBitSynchronizer::reset ()
```

Reset the synchronizer state.
Clears the histogram and all internal counters/flags, returning the instance to the pre-lock state:

- locked() becomes false
- edge_phase() becomes -1
- total_events and epoch_count are reset to zero

12.215.3.10 update()

```
bool HistogramBitSynchronizer::update (
            const std::complex< float > & prompt,
            bool tracking_quality_ok)
```

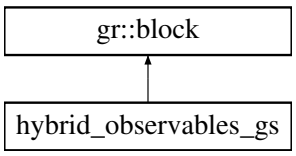
Update the synchronizer once per epoch.
This method should be called at a fixed cadence defined by Config::epoch_ms
The method:

- Advances the internal epoch counter,
- Optionally performs candidate transition detection if tracking quality is acceptable,
- Updates the phase histogram on detected transitions,
- Evaluates lock once enough events have been gathered.

Parameters

prompt	Prompt correlator output for the current epoch.
tracking_quality_ok	Indicates whether tracking quality is sufficient to trust the prompt sample for transition detection (e.g., code/carrier lock metrics).

Returns



True only on the epoch when lock is first declared; false otherwise (including subsequent epochs after lock has been achieved).

12.276.1 Detailed Description

Receives and decodes a fixed-base RTCM3 stream from an NTRIP caster, preferring NTRIP v2 with a fresh-connection fallback to v1, or using forced v1, optionally over TLS.
The object owns one worker thread. The public snapshot and status methods copy data under a mutex and can be called concurrently with the worker.

- int band_slot

- const char * signal

  two-character channel signal code (Gnss_Synchro convention)

12.280.1 Detailed Description

Single home for the signal knowledge of the NTRIP RTK path: which tracked signals it supports and, for each one, the constellation, the RTKLIB frequency slot it occupies, and the channel signal code. The adapter's channel-set validity predicate, its error message, its derived slot count and navigation-system mask, and the client's per-slot observation filter all derive from this table, and the solver cross-checks its own band mapping against it at construction — so admitting a new SIGNAL of a supported constellation is a one-row change (plus documentation and tests; a slot-sharing preference rule like BeiDou's prefer-B1C stays an explicit exception in the client). A new SYSTEM additionally needs base-side admission in the client and the solver, and navigation-system compatibility handling in the adapter.

12.285.1 Detailed Description

This abstract class represents an interface to an observables block.
Abstract class for pseudorange_intefaces, derived from GNSSBlockInterface. Since all its methods are virtual, this class cannot be instantiated directly, and a subclass can only be instantiated directly if all inherited pure virtual methods have been implemented by that class or a parent class.

12.320.1 Detailed Description

This class implements the Protocol Buffers library shared memory cleanup manager.
google::protobuf::ShutdownProtobufLibrary() must be called only once, at the end of the program execution: it is not safe to use any other part of the library after that call. Calling it earlier (e.g., from the destructor of a class that uses protobuf) results in use-after-free memory corruption and random crashes. Call Protobuf_Cleanup_Manager::get() in the constructor of every class that uses the protobuf library, so that google::protobuf::ShutdownProtobufLibrary() is called at program shutdown, when the singleton is destroyed.

12.335.2 Constructor & Destructor Documentation

12.335.2.1 ReedSolomon() [1/2]

```
ReedSolomon::ReedSolomon (
            const std::string & gnss_signal = std::string())  [explicit]
```

Default constructor. Constructs a Reed Solomon object. The encode_with_generator_poly and encode_with_↩ generator_matrix methods are available for testing purposes.
gnss_signal: empty or "E6B" sets the Galileo E6B RS parameters. "E1B" sets the Galileo E1B (INAV) RS parameters.

12.335.2.2 ReedSolomon() [2/2]

```
ReedSolomon::ReedSolomon (
            int nroots,
            int minpoly,
            int prim,
            int fcr,
            int pad = 0,
            int shortening = 0,
            const std::vector< uint8_t > & genpoly_coeff = std::vector< uint8_t >{},
            const std::vector< std::vector< uint8_t > > & gen_matrix = std::vector< std::vector< uint8_t >
```

Custom constructor for RS(255, 255-nroots, nroots+1). Parameters:
nroots - the number of roots in the RS code generator polynomial, which is the same as the number of parity symbols in a block.
minpoly - primitive polynomial.
prim - the primitive root of the generator polynomial.

fcr - first consecutive root of the Reed-Solomon generator polynomial.
pad - the number of pad symbols in a block. If not defined, it defaults to 0.
shortening - value of the shortening parameter. Defaults to 0. If different to 0, it defines a shortened RS encoder/↩ decoder.
genpoly_coeff - a vector of (nroots+1) elements containing the generator polynomial coefficients. Only used for encoding. Defaults to empty. If defined, the encode_with_generator_poly method can be used.
gen_matrix - a (255-shortening)x(255-nroots-shortening) matrix containing the elements of the generator matrix. Only used for encoding. Defaults to empty. If defined, the encode_with_generator_matrix method can be used.

12.335.3 Member Function Documentation

            std::vector< uint8_t > & data_to_decode,
            const std::vector< int > & erasure_positions = std::vector< int >{}) const
```

Decode an encoded block.
The decoded symbols are at the first 255-nroots-shortening elements of the data_to_decode vector.
The second parameter is optional, and contains a vector of erasure positions to be passed to the decoding algorithm. Defaults to empty.
Returns the number of corrected errors, or -1 if decoding failed.

            const std::vector< uint8_t > & data_to_encode) const
```

12.337.1 Detailed Description

This class implements the generation and reading of some Message Types defined in the RTCM 3.2 Standard, plus some utilities to handle messages.
Generation of the following Message Types: 1001, 1002, 1003, 1004, 1005, 1006, 1008, 1019, 1020, 1029, 1045, 1057, 1058, 1059, 1060
Decoding of the following Message Types: 1019, 1045
Generation of the following Multiple Signal Messages: MSM1 (message types 1071, 1091) MSM2 (message types 1072, 1092) MSM3 (message types 1073, 1093) MSM4 (message types 1074, 1094) MSM5 (message types 1075, 1095) MSM6 (message types 1076, 1096) MSM7 (message types 1077, 1097)
RTCM 3 message format (size in bits): +--------—+-------—+----------—+------------------—+--------—+ | preamble | 000000 | length | data message | parity | +----------—+-------—+----------—+------------------—+--------—+ |<– 8 –->|<- 6 -->|<– 10 –->|<— length x 8 –->|<– 24 –->| +--------—+-------—+----------—+------------------—+--------—+
